

Perforce Helix Core Server Deployment Package (for UNIX/Linux)

Perforce Professional Services

Version v2023.2, 2023-12-22

Table of Contents

Preface	1
1. Overview	2
1.1. Using this Guide	2
1.2. Getting the SDP	3
1.3. Checking the SDP Version	3
2. Setting up the SDP	4
2.1. Terminology Definitions	4
3. Pre-Requisites	6
3.1. Volume Layout and Hardware	6
4. Maintaining the SDP on Unix / Linux	8
4.1. Backup procedures	8
4.1.1. Metadata checkpoints	8
4.1.2. Backup of the partition containing depots, checkpoints, and the SDP configuration	8
4.2. Notifications	8
4.2.1. Configuration	8
4.2.2. Notifications to monitor	9
4.2.2.1. Daily Checkpoint	9
4.2.2.2. Verify	9
4.2.2.3. Sync Replica	9
4.3. Disk usage	9
5. Installing the SDP on Unix / Linux	10
5.1. Manual Install	10
5.1.1. Manual Install Initial setup	13
5.1.1.1. Use of SSL	14
5.1.1.2. Configuration script mkdirs.cfg	15
5.1.2. SDP Init Scripts	16
5.1.2.1. Configuring systemd	17
Configuring systemd for p4d	17
Configuring systemd for p4p	18
Configuring systemd for p4dtg	18
Configuring systemd p4broker - multiple configs	18
5.1.2.2. Enabling systemd under SELinux	21
5.1.2.3. Configuring SysV Init Scripts	22
5.1.3. Configuring Automatic Service Start on Boot	22
5.1.3.1. Automatic Start for Systems using systemd	22
5.1.3.2. For systems using the SysV init mechanism	23
5.1.4. SDP Crontab Templates	23
5.1.5. Completing Your Server Configuration	23

5.1.6. Validating your SDP installation	24
5.2. Local SDP Configuration	25
5.2.1. Load Order	26
5.3. Setting your login environment for convenience	26
5.4. Configuring protections, file types, monitoring and security	26
5.5. Operating system configuration	27
5.5.1. Configuring email for notifications	27
5.5.2. Swarm Email Configuration	28
5.5.3. Configuring PagerDuty for notifications	28
5.5.3.1. Prerequisites	28
5.5.3.2. SDP Configuration	28
5.5.3.3. Optional variables	29
Example Additional Context Configuration	29
5.5.4. Configuring AWS Simple Notification Service (SNS) for notifications	30
5.5.4.1. Prerequisites	30
5.5.4.2. SDP Configuration	30
5.5.4.3. Example IAM Policy	30
5.6. Other server configurables	31
5.7. Archiving configuration files	31
5.8. Installing Swarm Triggers	31
6. Backup, Replication, and Recovery	34
6.1. Typical Backup Procedure	34
6.2. Planning for HA and DR	35
6.2.1. Further Resources	36
6.2.2. Creating a Failover Replica for Commit or Edge Server	36
6.2.3. What is a Failover Replica?	36
6.2.4. Mandatory vs Non-mandatory Standbys	37
6.2.5. Server host naming conventions	38
6.3. Full One-Way Replication	39
6.3.1. Replication Setup	39
6.3.2. Replication Setup for Failover	39
6.3.3. Pre-requisites for Failover	39
6.3.4. Using mkrep.sh	40
6.3.4.1. SiteTags.cfg	40
6.3.4.2. Output of <code>mkrep.sh</code>	41
6.3.5. Addition Replication Setup	41
6.3.6. SDP Installation	41
6.3.6.1. SSH Key Setup	41
6.4. Recovery Procedures	42
6.4.1. Recovering a master server from a checkpoint and journal(s)	42
6.4.2. Recovering a replica from a checkpoint	43

6.4.3. Recovering from a tape backup	43
6.4.4. Failover to a replicated standby machine	44
7. Upgrades	45
7.1. Upgrade Order: SDP first, then Helix P4D	45
7.2. SDP and P4D Version Compatibility	45
7.3. Upgrading the SDP	45
7.3.1. Sample SDP Upgrade Procedure	46
7.3.2. SDP Legacy Upgrade Procedure	46
7.4. Upgrading Helix Software with the SDP	47
7.4.1. Get Latest Helix Binaries	47
7.4.2. Upgrade Each Instance	47
7.4.3. Global Topology Upgrades - Outer to Inner	47
7.5. Database Modifications	48
8. Maximizing Server Performance	50
8.1. Ensure Transparent Huge Pages (THP) is turned off	50
8.2. Putting server.locks directory into RAM	51
8.3. Installing monitoring packages	53
8.4. Optimizing the database files	53
8.5. P4V Performance Settings	54
8.6. Proactive Performance Maintenance	54
8.6.1. Limiting large requests	54
8.6.2. Offloading remote syncs	54
9. Tools and Scripts	55
9.1. General SDP Usage	55
9.1.1. Linux	55
9.1.2. Monitoring SDP activities	56
9.2. Upgrade Scripts	56
9.2.1. get_helix_binaries.sh	56
9.2.2. upgrade.sh	58
9.2.3. sdp_upgrade.sh	69
9.3. Legacy Upgrade Scripts	75
9.3.1. clear_depot_Map_fields.sh	75
9.4. Core Scripts	77
9.4.1. p4_vars	77
9.4.2. p4_<instance>.vars	78
9.4.3. p4master_run	78
9.4.4. daily_checkpoint.sh	78
9.4.5. keep_offline_db_current.sh	79
9.4.6. live_checkpoint.sh	79
9.4.7. mkrep.sh	80
9.4.8. p4verify.sh	86

9.4.9. p4login	98
9.4.10. p4d_<instance>_init	101
9.4.11. recreate_offline_db.sh	101
9.4.12. refresh_P4ROOT_from_offline_db.sh	101
9.4.13. run_if_master.sh	102
9.4.14. run_if_edge.sh	102
9.4.15. run_if_replica.sh	102
9.4.16. run_if_master/edge/replica.sh	102
9.4.17. sdp_health_check.sh	102
9.5. More Server Scripts	104
9.5.1. p4.crontab	104
9.5.2. verify_sdp.sh	104
9.6. Other Scripts and Files	107
9.6.1. backup_functions.sh	107
9.6.2. broker_rotate.sh	107
9.6.3. ccheck.sh	108
9.6.4. edge_dump.sh	110
9.6.5. edge_vars	110
9.6.6. edge_shelf_replicate.sh	110
9.6.7. load_checkpoint.sh	110
9.6.8. gen_default_broker_cfg.sh	117
9.6.9. journal_watch.sh	118
9.6.10. kill_idle.sh	119
9.6.11. mkdirs.sh	119
9.6.12. p4d_base	123
9.6.13. p4broker_base	124
9.6.14. p4ftpd_base	124
9.6.15. p4p_base	124
9.6.16. p4pcm.pl	124
9.6.17. p4review.py	124
9.6.18. p4review2.py	125
9.6.19. proxy_rotate.sh	125
9.6.20. p4sanity_check.sh	125
9.6.21. p4dstate.sh	126
9.6.22. ps_functions.sh	126
9.6.23. pull.sh	126
9.6.24. pull_test.sh	127
9.6.25. purge_revisions.sh	128
9.6.26. recover_edge.sh	129
9.6.27. replica_cleanup.sh	129
9.6.28. replica_status.sh	130

9.6.29. request_replica_checkpoint.sh	130
9.6.30. rotate_journal.sh	130
9.6.31. submit.sh	131
9.6.32. submit_test.sh	132
9.6.33. sync_replica.sh	132
9.6.34. templates directory	132
9.6.35. update_limits.py	133
10. Sample Procedures	134
10.1. Installing Python3 and P4Python	134
10.2. Installing CheckCaseTrigger.py	135
10.3. Swarm JIRA Link	136
10.4. Reseeding an Edge Server	137
10.5. Edge Reseed Scenario	137
10.5.1. Step 0: Preflight Checks	138
10.5.2. Step 1: Create New Edge Seed Checkpoint	138
10.5.3. Step 2: Transfer Edge Seed	139
10.5.4. Step 3: Reseed the Edge	139
Appendix A: SDP Package Contents and Planning	141
A.1. Volume Layout and Server Planning	141
A.1.1. Memory and CPU	141
A.1.2. Directory Structure Configuration Script for Linux/Unix	142
A.1.3. P4D versions and links	143
A.1.4. Case Insensitive P4D on Unix	144
Appendix B: The journalPrefix Standard	146
B.1. SDP Scripts that set journalPrefix	146
B.2. First Form of journalPrefix Value	146
B.2.1. Detail on "Completely Unfiltered"	146
B.3. Second Form of journalPrefix Value	147
B.4. Scripts for Maintaining the offline_db	147
B.5. SDP Structure and journalPrefix	148
B.6. Replicas of Edge Servers	148
B.7. Goals of the journalPrefix Standard	149
Appendix C: Server Spec Naming Standard	150
C.1. General Form	150
C.1.1. Helix Server Tags	150
C.1.2. Replica Type Tags	150
C.1.2.1. Replication Notes	151
C.1.3. Site Tags	151
C.2. Example Server Specs	152
C.3. Implications of Replication Filtering	152
C.4. Other Replica Types	152

C.5. The SDP <code>mkrep.sh</code> script	152
Appendix D: Frequently Asked Questions	153
D.1. How do I tell what version of the SDP I have?	153
D.2. How do I change super user password?	153
D.3. Can I remove the performce user?	154
D.4. Can I clone a VM to create a standby replica?	155
Appendix E: Troubleshooting Guide	157
E.1. <code>Daily_checkpoint.sh</code> fails	157
E.1.1. Last checkpoint not complete. Check the backup process or contact support.	157
E.2. Replication appears to be stalled	157
E.2.1. Resolution	158
E.2.2. Make Errors Visible	159
E.2.3. Remove state file	159
E.3. Archive pull queue appears to be stalled	160
E.3.1. Resolutions	160
E.3.1.1. Remove and re-queue	160
E.3.1.2. Check for verify errors on the parent server	161
E.4. Can't login to edge server	161
E.4.1. Resolution	161
E.5. Updating <code>offline_db</code> for an edge server	161
E.5.1. Resolution	161
E.6. Journal out of sequence in <code>checkpoint.log</code> file	162
E.7. Unexpected end of file in replica daily sync	163
Appendix F: Starting and Stopping Services	164
F.1. SDP Service Management with the <code>systemd</code> init mechanism	164
F.1.1. Brokers and Proxies	165
F.1.2. Root or sudo required with <code>systemd</code>	165
F.2. SDP Service Management with SysV init mechanism	165
Appendix G: Brokers in Stack Topology	167
Appendix H: SDP Health Checks	168

Preface

The Server Deployment Package (SDP) is the implementation of Perforce's recommendations for operating and managing a production Perforce Helix Core Version Control System. It is intended to provide the Helix Core administration team with tools to help:

- Simplify Management
- Simplify Upgrades
- High Availability (HA)
- Disaster Recovery (DR)
- Fast and Safe Upgrades
- Production Focus
- Best Practice Configurables
- Optimal Performance, Data Safety, and Simplified Backup

This guide is intended to provide instructions of setting up the SDP to help provide users of Helix Core with the above benefits.

This guide assumes some familiarity with Perforce and does not duplicate the basic information in the Perforce user documentation. This document only relates to the Server Deployment Package (SDP). All other Helix Core documentation can be found here: [Perforce Support Documentation](#).

Please Give Us Feedback

Perforce welcomes feedback from our users. Please send any suggestions for improving this document or the SDP to consulting@perforce.com.

Chapter 1. Overview

The SDP has four main components:

- Hardware and storage layout recommendations for Perforce.
- Scripts to automate critical maintenance activities.
- Scripts to aid the setup and management of replication (including failover for DR/HA).
- Scripts to assist with routine administration tasks.

Each of these components is covered, in detail, in this guide.

1.1. Using this Guide

[Chapter 2, *Setting up the SDP*](#) describes concepts, terminology and pre-requisites

[Chapter 4, *Maintaining the SDP on Unix / Linux*](#) covers administrative duties associated with keeping an installation of the SDP in good shape.

[Chapter 5, *Installing the SDP on Unix / Linux*](#) consists of what you need to know to setup Helix Core sever on a Unix platform.

[Chapter 6, *Backup, Replication, and Recovery*](#) gives information around the Backup, Restoration and Replication of Helix Core, including some guidance on planning for HA (High Availability) and DR (Disaster Recovery)

[Chapter 7, *Upgrades*](#) covers upgrades of `p4d` and related Helix Core executables.

[Section 7.3, “Upgrading the SDP”](#) covers upgrading the SDP itself.

[Chapter 8, *Maximizing Server Performance*](#) covers optimizations and proactive actions.

[Chapter 9, *Tools and Scripts*](#) covers all the scripts used within the SDP in detail.

[Appendix A, *SDP Package Contents and Planning*](#) describes the details of the SDP package.

[Appendix B, *The journalPrefix Standard*](#) describes the standard for setting the `journalPrefix` configurable.

[Appendix C, *Server Spec Naming Standard*](#) describes the standard for naming 'server' specs created with the `p4 server` command.

[Appendix D, *Frequently Asked Questions*](#) and [Appendix E, *Troubleshooting Guide*](#) are useful for other questions.

[Appendix F, *Starting and Stopping Services*](#) gives on overview of starting and stopping services with common init mechanisms, `systemd` and SysV.

1.2. Getting the SDP

The SDP is downloaded as a single zipped tar file the latest version can be found at: <https://swarm.workshop.perforce.com/projects/perforce-software-sdp/files/downloads>

The file to download containing the latest SDP is consistently named `sdp.Unix.tgz`. A copy of this file also exists with a version-identifying name, e.g. `sdp.Unix.2021.2.28649.tgz`.

The direct download link to use with `curl` or `wget` is illustrated with this command:

```
curl -L -O https://swarm.workshop.perforce.com/projects/perforce-software-sdp/download/downloads/sdp.Unix.tgz
```

1.3. Checking the SDP Version

Once installed, the SDP `Version` file exists as `/p4/sdp/Version`. This is a simple text file that contains the SDP version string. The version can be checked using a command like `cat`, as in this sample command:

```
$ cat /p4/sdp/Version
Rev. SDP/MultiArch/2020.1/27955 (2021/08/13)
```

That string can be found in Change History section of the [SDP Release Notes](#). This can be useful in determining if your SDP is the latest available, and to see what features are included.

When an SDP tarball is extracted, the `Version` file appears in the top-level `sdp` directory.

Chapter 2. Setting up the SDP

This section tells you how to configure the SDP to setup a new Helix Core server.

The SDP can be installed on multiple server machines, and each server machine can host one or more Helix Core server instances. See [Section 2.1, “Terminology Definitions”](#) for detailed definition of terms.

The SDP implements a standard logical directory structure which can be implemented flexibly on one or many physical server machines.

Additional relevant information is available in the [System Administrator Guide](#).

2.1. Terminology Definitions

- **process** - a running process with a process identifier (PID). It should normally be qualified as to what type of process it is:
 - **p4d process** - a running p4d process with its own copy of db.* files. P4D processes may be of any one of the standard types, e.g. standard or commit-server, and any of the valid replica types: standby, forwarding-replica, edge-server etc.
 - **p4p process** – proxy instance talking to a single upstream p4d instance
 - **p4broker process** – p4broker talking to a single upstream p4d instance
- **Instance** - a logically independent set of Helix Core data and metadata, represented by entities such as changelist numbers and depot paths, and existing a storage device in the form of db.* files (metadata) and versioned files (archive files). Thus, the instance is a reference to the logical data set, with its set of users, files, changelists.
 - The default SDP instance name is simply **1** (the digit 'one').
 - Any alphanumeric name can be used. It is mainly of interest to administrators, not regular users.
 - Instance names are best kept short, as they are typed often in various admin operational tasks.
 - An **instance** has a well defined name, embedded in its P4ROOT value. If the P4ROOT is `/p4/ace/root`, for example, **ace** is the instance name.
 - An **instance** must operate with at least one p4d process on a master server machine. The instance may also extend to many machines running additional p4d, p4broker, and p4p processes. For the additional p4d processes, they can be replicas of various types, to include standby, edge, and filtered forwarding replicas (to name a few).
 - On all machines on which an instance is physically extended, including proxy, broker, and replica machines, the instance exists as `/p4/N`, where **N** is the instance name.
 - There can be more than one instance a machine.
- **Server machine** - this is a host machine (virtual or physical) with operating system and on which any number of p4d or other processes may be running.

- **Server spec** or **server specification** - is the entity managed using `p4 server` command (and the companion `p4 servers` to list all of them).
- **Server** - this is a vague term. It needs to be fully qualified, and use on its own (unadorned) depends on context. It may mean any one of:
 - Server machine
 - P4d process (this is usually the most common usage - tend to assume this unless otherwise defined.)
 - Any other type of instance!

Thus "p4d server" is unclear as to whether you are talking about a p4d process or a server machine or a combination of both (since there may be a single instance on a single machine, or many instances on a machine, etc). Make sure you understand what is being referred to!

Chapter 3. Pre-Requisites

1. The Helix Core binaries (p4d, p4, p4broker, p4p) have been downloaded (see [Chapter 5, Installing the SDP on Unix / Linux](#))
2. `sudo` access is required
3. System administrator available for configuration of drives / volumes (especially if on network or SAN or similar)
4. Supported Linux version, currently these versions are fully supported - for other versions please speak with Perforce Support.
 - Ubuntu 18.04 LTS (bionic)
 - Ubuntu 20.04 LTS (focal)
 - Red Hat Enterprise Linux (RHEL) 7.x
 - Red Hat Enterprise Linux (RHEL) 8.x
 - CentOS 7
 - CentOS 8 (not recommended for production; Rocky Linux replaces CentOS 8)
 - Rocky Linux 8.x
 - SUSE Linux Enterprise Server 12

3.1. Volume Layout and Hardware

As can be expected from a version control system, good disk (storage) management is key to maximizing data integrity and performance. Perforce recommend using multiple physical volumes for **each** p4d server instance. Using three or four volumes per instance reduces the chance of hardware failure affecting more than one instance. When naming volumes and directories the SDP assumes the "hx" prefix is used to indicate Helix volumes. Your own naming conventions/standards can be used instead, though this is discouraged as it will create inconsistency with documentation. For optimal performance on UNIX machines, the XFS file system is recommended, but not mandated. The EXT4 filesystem is also considered proven and widely used.

- **Depot data, archive files, scripts, and checkpoints:** Use a large volume, with RAID 6 on its own controller with a standard amount of cache or a SAN or NAS volume (NFS access is fine).

This volume is the only volume that **must** be backed up. The SDP backup scripts place the metadata snapshots on this volume.

+ This volume is normally called `/hxdepots`.

- **Perforce metadata (database files), 1 or 2 volumes:** Use the fastest volume possible, ideally SSD or RAID 1+0 on a dedicated controller with the maximum cache available on it. Typically a single volume is used, `/hxmetadata`. In some sites with exceptionally large metadata, 2 volumes are used for metadata, `/hxmetadata` and `/hxmetadata2`. Exceptionally large in this case means the metadata size on disk is such that $(2 \times (\text{size of db.* files}) + \text{room for growth})$ approaches or exceeds the storage capacity of the storage device used for metadata. That's driven by how big

/hxmetadata volume. So if you have a 16T storage volume and your total size of db.* files is some ~7T or less (so ~14T total), that's probably a reasonable cutoff for the definition of "exceptionally large" in this context.

Do not run anti-virus tools or back up tools against the `hxmetadata` volume(s) or `hxlogs` volume(s), because they can interfere with the operation of the Perforce server executable.

- **Journals and logs:** a fast volume, ideally SSD or RAID 1+0 on its own controller with the standard amount of cache on it. This volume is normally called `/hxlogs` and can optionally be backed up.

If a separate logs volume is not available, put the logs on the `/hxmetadata` or `/hxmetadata1` volume, as metadata and logs have similar performance needs that differ from `/hxdepots`.

Storing metadata and logs on the same volume is discouraged, since the redundancy benefit of the P4JOURNAL (stored on `/hxlogs`) is greatly reduced if P4JOURNAL is on the same volume as the metadata in the P4ROOT directory.

If multiple controllers are not available, put the `/hxlogs` and `/hxdepots` volumes on the same controller.

On all SDP machines, a `/p4` directory will exist containing a subdirectory for each instance, and each instance named `/p4`. The volume layout is shown in [Appendix A, SDP Package Contents and Planning](#). This `/p4` directory enables easy access to the different parts of the file system for each instance.

For example:

- `/p4/1/root` contains the database files for instance 1
- `/p4/1/logs` contains the log files for instance 1
- `/p4/1/bin` contains the binaries and scripts for instance 1
- `/p4/common/bin` contains the binaries and scripts common to all instances

Chapter 4. Maintaining the SDP on Unix / Linux

4.1. Backup procedures

Helix Core's purpose is to maintain long-running history of all your development. As such, it is important to take reliable backups to preserve your dataset integrity.

4.1.1. Metadata checkpoints

The SDP contains scripts and a default crontab which will create daily checkpoints with no downtime. The script [Section 9.4.4, “daily_checkpoint.sh”](#) accomplishes this by rotating the journal, replaying it into the `offline_db` directory, and checkpointing the `offline_db` directory. The resulting checkpoints, rotated journals, and checkpoint checksum files can be found in `/p4/<instance>/checkpoints`.

It is difficult to overstate the importance of regular checkpoints. Perforce metadata (the `db.*` files) is in a constant state of flux, and a checkpoint is the most reliable point of recovery for a commit server. Attempts to back up the `root` directory with `cp` or `rsync` will result in a metadata set that is probably inconsistent and corrupt. Simple backups of the root directory are insufficient.

4.1.2. Backup of the partition containing depots, checkpoints, and the SDP configuration

There are three important parts to an SDP installation of Perforce: Metadata, archive storage (back-end version file storage), and configuration. A standard SDP installation will have all three of these on the `/hxdepots` partition or equivalent. Whatever your server backup strategy is, ensure that you are taking regular snapshots of `/hxdepots`.

4.2. Notifications

The SDP contains the framework to allow your server to communicate its automated maintenance activities, both successes and failures. It is important to ensure that the SPD is properly configured to send emails to the right people, and that the right people are monitoring their emails.

4.2.1. Configuration

Setting up mailx, postfix, or mailutils will allow your server to send out emails to your administrative team. Details can be found in [Section 5.5.1, “Configuring email for notifications”](#).

To tell the SDP whom to mail, you will need to set that in the file `/p4/common/config/p4_<instance.vars>` on a per-instance basis. The relevant lines are:

```
export MAILTO=P4AdminList@p4demo.com
```

```
export MAILFROM=P4Admin@p4demo.com
```

The `MAILTO` value can be a distribution group like `administrators@company.net`, a single recipient like `bruno@company.net`, or a comma delimited list like `bruno@company.net,mary@company.net,pat@company.net`.

The `MAILFROM` value can be a valid email address, or a placeholder like `do-not-reply@company.net`.

4.2.2. Notifications to monitor

Your administrator should be aware of the emails that the SDP will be sending on a regular basis. Be careful to not simply redirect them into an unmonitored folder.

4.2.2.1. Daily Checkpoint

Probably the most important notification to follow, the daily checkpoint job lets you know that your metadata is backed up. Any error messages should be investigated.

4.2.2.2. Verify

By default, the SDP will run a verify on all your back-end versioned file storage on a weekly basis. It is possible that errors or warnings will creep into an instance as time goes on. These should be investigated, but they are often not mission-critical.

4.2.2.3. Sync Replica

If you are in a Helix topology that contains replicas or edges, those machines will have their own automated jobs that synchronize checkpoints from the commit server, and keep the metadata in sync. To maintain a healthy topology, these emails should also be investigated if they contain errors.

4.3. Disk usage

Running out of disk is never fun. You should keep an eye on your disk usage, expanding when needed. A default SDP instance has the following configurables set:

```
filesystem.P4JOURNAL.min = 5G
```

```
filesystem.P4ROOT.min = 5G
```

```
filesystem.depot.min = 5G
```

These settings will cause Perforce to halt when they discover that free disk space is under 5G on the specified partition. This will spare you from corruption if Perforce tries to write to a database and isn't able to finish. *However*, there are some edge cases where disk usage can still be disruptive. If your total partition size is 5G or lower, Perforce will halt automatically even if 5G was your intended partition size. Monitoring and expanding your storage space is an important part of maintenance.

Chapter 5. Installing the SDP on Unix / Linux

5.1. Manual Install

The following documentation covers internal details of how the SDP can be deployed manually.

To install Perforce Helix Core server and the SDP, perform the steps laid out below:

- Set up a user account, file system, and configuration scripts.
- Run the configuration script.
- Start the p4d process and configure the required file structure for the SDP.

1. If it doesn't already exist, create a group called `perforce`:

```
sudo groupadd perforce
```

2. Create a user called `perforce` and set the user's home directory to `/home/perforce` on a local disk. We recommend using a local rather than automounted home directory for the `perforce` OS user. Using an automounted home directory introduces new failure modes for p4d, as well as potential performance issues. A local directory on the local storage is recommend for the home directory. (If the `/home` directory is always automounted, consider using something else, like `/usr/local/home/perforce` in the example below):

```
sudo useradd -d /home/perforce -s /bin/bash -m perforce -g perforce
```

3. Allow the perforce user sudo access - Option 1 (full sudo)

```
sudo touch /etc/sudoers.d/perforce
sudo chmod 0600 /etc/sudoers.d/perforce
sudo echo "perforce ALL=(ALL) NOPASSWD:ALL" > /etc/sudoers.d/perforce
sudo chmod 0400 /etc/sudoers.d/perforce
```

4. Allow the perforce user sudo access - Option 2 (limited sudo)

```
sudo touch /etc/sudoers.d/perforce
sudo chmod 0600 /etc/sudoers.d/perforce
vi /etc/sudoers.d/perforce
```

5. In the text editor, make the file look like this to give limited sudo, replacing `EDTIME_HOSTNAME` with the current machine:

```
Cmdnd_Alias P4_SVC = /usr/bin/systemctl start node_exporter, \
    /usr/bin/systemctl stop node_exporter, \
```

```

/usr/bin/systemctl restart node_exporter, \
/usr/bin/systemctl status node_exporter, \
/usr/bin/systemctl cat node_exporter, \
/usr/bin/systemctl enable node_exporter, \
/usr/bin/systemctl disable node_exporter, \
/usr/bin/systemctl is-enabled node_exporter, \
/usr/bin/systemctl start p4d_*, \
/usr/bin/systemctl stop p4d_*, \
/usr/bin/systemctl restart p4d_*, \
/usr/bin/systemctl status p4d_*, \
/usr/bin/systemctl cat p4d_*, \
/usr/bin/systemctl enable p4d_*, \
/usr/bin/systemctl disable p4d_*, \
/usr/bin/systemctl is-enabled p4d_*, \
/usr/bin/systemctl start p4dtg_*, \
/usr/bin/systemctl stop p4dtg_*, \
/usr/bin/systemctl restart p4dtg_*, \
/usr/bin/systemctl status p4dtg_*, \
/usr/bin/systemctl cat p4dtg_*, \
/usr/bin/systemctl enable p4dtg_*, \
/usr/bin/systemctl disable p4dtg_*, \
/usr/bin/systemctl is-enabled p4dtg_*, \
/usr/bin/systemctl start p4broker_*, \
/usr/bin/systemctl stop p4broker_*, \
/usr/bin/systemctl restart p4broker_*, \
/usr/bin/systemctl status p4broker_*, \
/usr/bin/systemctl cat p4broker_*, \
/usr/bin/systemctl enable p4broker_*, \
/usr/bin/systemctl disable p4broker_*, \
/usr/bin/systemctl is-enabled p4broker_*, \
/usr/bin/systemctl start p4p_*, \
/usr/bin/systemctl stop p4p_*, \
/usr/bin/systemctl restart p4p_*, \
/usr/bin/systemctl status p4p_*, \
/usr/bin/systemctl cat p4p_*, \
/usr/bin/systemctl enable p4p_*, \
/usr/bin/systemctl disable p4p_*, \
/usr/bin/systemctl is-enabled p4p_*, \
/usr/bin/systemctl start p4prometheus*, \
/usr/bin/systemctl stop p4prometheus*, \
/usr/bin/systemctl restart p4prometheus*, \
/usr/bin/systemctl status p4prometheus*, \
/usr/bin/systemctl cat p4prometheus*, \
/usr/bin/systemctl enable p4prometheus*, \
/usr/bin/systemctl disable p4prometheus*, \
/usr/bin/systemctl is-enabled p4prometheus*, \
/usr/bin/getcap, \
/usr/bin/setcap, \
/usr/sbin/setcap, \
/usr/sbin/getcap, \
/sbin/getcap, \

```

```

/sbin/setcap, \
/bin/getcap, \
/bin/setcap
performce EDITME_HOSTNAME = (root) NOPASSWD: P4_SVC

```

6. Then lock down the file:

```
sudo chmod 0400 /etc/sudoers.d/performce
```

7. Create or mount the OS server file system volumes (per layout in previous section)

- /hxdepots
- /hxlogs

and either:

- /hxmetadata

or

- /hxmetadata1
- /hxmetadata2

8. These directories should be owned by: `performce:performce`

```
sudo chown -R performce:performce /hx*
```

9. (Optional) if you have different root directories, or are putting all files into one mounted filesystem (only recommended for small repositories), then do something like the following:

Option 1, all under a single directory `/data`:

```

cd /data
mkdir hxmetadata hxlogs hxdepots
sudo chown -R performce:performce /data/hx*
cd /
ln -s /data/hx* .
sudo chown -h performce:performce /hx*

```

Option 2, different mounted root folders, e.g. `/P4metadata`, `/P4logs`, `/P4depots`:

```

sudo chown -R performce:performce /P4metadata /P4logs /P4depots
ln -s /P4metadata /hxmetadata
ln -s /P4logs /hxlogs
ln -s /P4depots /hxdepots
sudo chown -h performce:performce /hx*

```

10. Extract the SDP tarball.

```
cd /hxdepots
tar -xzf /WhereYouDownloaded/sdp.Unix.tgz
```

11. Set environment variable SDP.

```
export SDP=/hxdepots/sdp
```

12. Make the entire \$SDP (/hxdepots/sdp) directory writable by `perforce:perforce` with this command:

```
chmod -R +w $SDP
```

13. Download the appropriate p4, p4d and p4broker binaries for your release and platform:

```
cd /hxdepots/sdp/helix_binaries
./get_helix_binaries.sh
```

If you want to specify a particular release, use the `-r` option as in this example specifying the r20.2 release:

```
cd /hxdepots/sdp/helix_binaries
./get_helix_binaries.sh -r r20.2
```

5.1.1. Manual Install Initial setup

The next steps highlight the setup and configuration of a new Helix Core instance using the `mkdirs.sh` script included in the SDP. Please refer to [Section 9.6.11, “mkdirs.sh”](#) for the full usage statement.

If you use a "name" for the instance (not an integer) you MUST modify the P4PORT variable in the `mkdirs.instance.cfg` file.

The instance name must map to the name of the cfg file or the default file will be used with potentially unexpected results.

Examples:

- `mkdirs.sh 1` requires `mkdirs.1.cfg`
- `mkdirs.sh ion` requires `mkdirs.ion.cfg`

3. Put the Perforce license file for the p4d server instance into `/p4/1/root`

if you have multiple instances and have been provided with port-specific licenses by Perforce, the appropriate license file must be stored in the appropriate `/p4/<instance>/root` folder.

the license file must be renamed to simply the name `license`.

Your Helix Core instance is now setup, but not running. The next steps detail how to make the Helix Core p4d instance a system service.

You are then free to start up the `p4d` instance as documented in [Appendix F, Starting and Stopping Services](#).

Please note that if you have configured SSL, then refer to [Section 5.1.1.1, “Use of SSL”](#).

5.1.1.1. Use of SSL

As documented in the comments in `mkdirs.cfg`, if you are planning to use SSL you need to set the value of:

```
SSL_PREFIX=ssl:
```

Then you need to put certificates in `/p4/ssl` after the SDP install or you can generate a self signed certificate as follows:

Edit `/p4/ssl/config.txt` to put in the info for your company. Then run:

```
/p4/common/bin/p4master_run <instance> /p4/<instance>/bin/p4d_<instance> -Gc
```

For example using instance 1:

```
/p4/common/bin/p4master_run 1 /p4/1/bin/p4d_1 -Gc
```

In order to validate that SSL is working correctly:

```
source /p4/common/bin/p4_vars 1
```

Check that `P4TRUST` is appropriately set in the output of:

```
p4 set
```

Update the `P4TRUST` values:

```
p4 trust -y
p4 -p ssl:$HOSTNAME:1666 trust -y # Assuming correct port
```

```
p4 -p $P4MASTERPORT trust -y
```

Check the stored P4TRUST values:

```
p4 trust -l
```

You need to have an entry for the above for both loopback (127.0.0.1 and the IP address of current machine)

Check you are not prompted for trust:

```
p4 login
p4 info
```

5.1.1.2. Configuration script makedirs.cfg

The `makedirs.sh` script executed above resides in `$SDP/Server/Unix/setup`. It sets up the basic directory structure used by the SDP. Carefully review the config file `makedirs.instance.cfg` for this script before running it, and adjust the values of the variables as required. The important parameters are:

Parameter	Description
DB1	Name of the hxmetadata1 volume (can be same as DB2)
DB2	Name of the hxmetadata2 volume (can be same as DB1)
DD	Name of the hxdepots volume
LG	Name of the hxlogs volume
CN	Volume for /p4/common
SDP	Path to SDP distribution file tree
SHAREDDATA	TRUE or FALSE - whether sharing the /hxdepots volume with a replica - normally this is FALSE
ADMINUSER	P4USER value of a Perforce super user that operates SDP scripts, typically <code>perforce</code> .
OSUSER	Operating system user that will run the Perforce instance, typically <code>perforce</code> .
OSGROUP	Operating system group that OSUSER belongs to, typically <code>perforce</code> .
CASE_SENSITIVE	Indicates if p4d server instance has special case sensitivity settings
SSL_PREFIX	Set if SSL is required so either "ssl:" or blank for no SSL

Parameter	Description
P4ADMINPASS	Password to use for Perforce superuser account - can be edited later in <code>/p4/common/config/.p4password.p4_1.admin</code>
P4SERVICEPASS	This value is not used by any SDP scripts or standard procedures. It is left in place for backward compatibility.
P4MASTERHOST	Fully qualified DNS name of the Perforce master server machine for this instance. should refer to the DNS of the edge server machine. Otherwise replicas should refer to the commit-server machine.

For a detailed description of this config file it is fully documented with in-file comments, or see

5.1.2. SDP Init Scripts

The SDP includes templates for initialization scripts ("init scripts") that provide basic service `start` /`stop`/`status` functionality for a variety of Perforce server products, including:

- p4d
- p4broker
- p4p
- p4dtg

During initialization for an SDP instance, the SDP `mkdirs.sh` script creates a set of initialization scripts based on the templates, and writes them in the instance-specific bin folder (the "Instance Bin" directory), `/p4/N/bin`. For example, the `/p4/1/bin` folder for instance 1 might contain any of the following:

```
p4d_1_init
p4broker_1_init
p4p_1_init
p4dtg_1_init
```

The set of `*_init` files in the Instance Bin directory defines which services (p4d, p4broker, p4p, and/or p4dtg) are active for the given instance on the current machine. A common configuration is to run both p4d and p4broker together, or only run a p4p on a machine. Unused init scripts must be removed from the Instance Bin dir. For example, if a p4p is not needed for instance 1 on the current machine, then `/p4/1/bin/p4p_1_init` should be removed.

For example, the init script for starting p4d for instance 1 is `/p4/1/bin/p4d_1_init`. All init scripts accept at least `start`, `stop`, and `status` arguments. How the init scripts are called depends on whether your operating system uses the `systemd` or older `SysV` init mechanism. This is detailed in sections specific to each init mechanism below.

Templates for the init scripts are stored in:

```
/p4/common/etc/init.d
```

5.1.2.1. Configuring systemd

Configuring systemd for p4d

RHEL/CentOS 7 or 8, SuSE 12, Ubuntu (>= v16.04), Amazon Linux 2, and other Linux distributions utilize **systemd** / **systemctl** as the mechanism for controlling services, replacing the earlier SysV init process. Templates for systemd *.service files are included in the SDP distribution in [\\$SDP/Server/Unix/p4/common/etc/systemd/system](#).

Note that using **systemd** is strongly recommended on systems that support it, for safety reasons. However, enabling services to start automatically on boot is optional.

To configure p4d for systemd, run these commands as the root user:

```
I=1
```

Replace the **1** on the right side of the **=** with your SDP instance name, e.g. xyz if your P4ROOT is /p4/xyz/root. Then:

```
cd /etc/systemd/system
sed -e "s:__INSTANCE__:${I}:g" -e "s:__OSUSER__:perforce:g"
$SDP/Server/Unix/p4/common/etc/systemd/system/p4d_N.service.t > p4d_${I}.service
chmod 644 p4d_${I}.service
systemctl daemon-reload
```

If you are configuring p4d for more than one instance, repeat the **I=** command with each instance name on the right side of the **=**, and then repeat the block of commands above.

Once configured, the following are sample management commands to start, stop, and status the service. These following commands are typically run as the **perforce** OSUSER using **sudo** where needed:

```
systemctl cat p4d_1
systemctl status p4d_1
sudo systemctl start p4d_1
sudo systemctl stop p4d_1
```

if running with SELinux in enforcing mode, see [Section 5.1.2.2, “Enabling systemd under SELinux”](#)

Systemd Required if Configured

If you are using `systemd` and you have configured services as above, then you can no longer run the `*_init` scripts directly for normal service `start/stop`, though they can still be used for `status`. The `sudo systemctl` commands **must** be used for `start/stop`. Attempting to run the underlying scripts directly will result in an error message if `systemd` is configured. This is for safety: `systemd`'s concept of service status (up or down) is only reliable when `systemd` starts and stops the service itself. The SDP init scripts require the `systemd` mechanism (using the `systemctl` command) to be used if it is configured. This ensures that services will gracefully stop the service on reboot (which would otherwise present a risk of data corruption for `p4d` on reboot).

The SDP requires `systemd` to be used if it is configured, and we strongly recommend using `systemd` on systems that use it. We recommend this to eliminate the risk of corruption on reboot, and also for consistency of operations. However, the SDP does not require `systemd` to be used. The SDP uses `systemctl cat` of the service name (e.g. `p4d_1`) to determine if `systemd` is configured for any given service.

Configuring `systemd` for `p4p`

Configuring `p4p` for `systemd` is identical to the configuration the for `p4d`, except that you would replace `p4d` with `p4p` in the sample commands above for configuring `p4d`.

Note SELinux fix ([Section 5.1.2.2, "Enabling `systemd` under SELinux"](#)) may be similarly required.

Configuring `systemd` for `p4dtg`

Configuring `p4dtg` for `systemd` is identical to the configuration the for `p4d`, except that you would replace `p4d` with `p4dtg` in the sample commands above for configuring `p4d`.

Note SELinux fix ([Section 5.1.2.2, "Enabling `systemd` under SELinux"](#)) may be similarly required.

Configuring `systemd` `p4broker` - multiple configs

Configuring `p4broker` for `systemd` can be similar to configuration the for `p4d`, but there are extra options as you may choose to run multiple broker configurations. For example, you may have:

- a default `p4broker` configuration that runs when the service is live,
- a "Down for Maintenance" (DFM) broker used in place of the default broker during maintenance to help lock out users broadcasting a friendly message like "Perforce is offline for scheduled maintenance."
- SSL broker config enabling an SSL-encrypted connection to a server that might not yet require SSL encryption for all users.

The service name for the default broker configuration is always `p4broker_N`, where `N` is the instance

name, e.g. `p4broker_1` for instance `1`. This uses the default broker config file, `/p4/common/config/p4_1.broker.cfg`.

Host Specific Broker Config

For circumstances where host-specific broker configuration is required, the default broker will use a `/p4/common/config/p4_N.broker.<short-hostname>.cfg` if it exists, where `<short-hostname>` is whatever is returned by the command `hostname -s`. The logic in the broker init script will favor the host-specific config if found, otherwise it will use the standard broker config.

When alternate broker configurations are used, each alternate configuration file must have a separate systemd unit file associated with managing that configuration. The service file must specify a configuration tag name, such as 'dfm' or 'ssl'. That tag name is used to identify both the broker config file and the systemd unit file for that broker. If the broker config is intended to run concurrently with the default broker config, it must listen on a different port number than the one specified in the default broker config. If it is only intended to run in place of the standard config, as with a 'dfm' config, then it should listen on the same port number as the default broker if a default broker is used, or else the same port as the p4d server if brokers are used only for dfm. The systemd service for a broker intended to run only during maintenance should not be enabled, and thus only manually started/stopped as part of maintenance procedures.

If maintenance procedures involve a reboot of a server machine, you may also want to disable all services during maintenance and re-enable them afterward.

For example, say you want a default broker, a DFM broker, and an SSL broker for instance 1. The default and SSL brokers will run continuously, and the DFM broker only during scheduled maintenance. The following broker config files would be needed in `/p4/common/config`:

- `p4_1.broker.cfg` - default broker, targets p4d on port 1999, listens on port 1666
- `p4_1.broker.ssl.cfg` - SSL broker, targets p4d on port 1999, listens on port 1667
- `p4_1.broker.dfm.cfg` - DFM broker, targets p4d on port 1999, listens on port 1666.

Then, create a systemd *.service file that references each config. For the default broker, use the template just as with p4d above. Do the following as the `root` user:

```
I=1
```

Replace the `1` on the right side of the `=` with your SDP instance name, e.g. `xyz` if your P4ROOT is `/p4/xyz/root`. Then:

```
cd /etc/systemd/system
sed -e "s:__INSTANCE__:${I}:g" -e "s:__OSUSER__:perforce:g"
$SDP/Server/Unix/p4/common/etc/systemd/system/p4broker_N.service.t >
p4broker_${I}.service
```

```
chmod 644 p4broker_$.service
systemctl daemon-reload
```

Once configured, the following are sample management commands to start, stop, and status the service. These following commands are typically run as the `perforce` OSUSER using `sudo` where needed:

```
systemctl cat p4broker_1
systemctl status p4broker_1
sudo systemctl start p4broker_1
sudo systemctl stop p4broker_1
```

For the non-default broker configs for the SSL and DFM brokers, start by copying the default broker config to a new `*.service` file with `_ssl` or `_dfm` inserted into the name, like so:

```
cd /etc/systemd/system
cp p4broker_1.service p4broker_1_dfm.service
cp p4broker_1.service p4broker_1_ssl.service
```

Next, modify the `p4broker_1_dfm.service` file and `p4broker_1_ssl.service` files with a text editor, making the following edits:

- Find the string that says `using default broker config`, and change the word `default` to `dfm` or `ssl` as appropriate, so it reads something like `using dfm broker config`.
- Change the `ExecStart` and `ExecStop` definitions by appending the `dfm` or `ssl` tag. For example, change these two lines:

```
ExecStart=/p4/1/bin/p4broker_1_init start
ExecStop=/p4/1/bin/p4broker_1_init stop
```

to look like this for the `dfm` broker:

```
ExecStart=/p4/1/bin/p4broker_1_init start dfm
ExecStop=/p4/1/bin/p4broker_1_init stop dfm
```

After any modifications to `systemd *.services` files are made, reload them into with:

```
systemctl daemon-reload
```

At this point, the services `p4broker_1`, `p4broker_1_dfm`, and `p4broker_1_ssl` can be started and stopped normally.

Finally, enable those services you want to start on boot. In our example here, we will enable the default and `ssl` broker services to start on boot, but not the DFM broker:

```
systemctl enable p4broker_1
systemctl enable p4broker_1_ssl
```

You must be aware of which configurations listen on the same port, and not try to runs those configurations concurrently. In this case, ensure the default and dfm brokers don't run at the same time. So, for example, you might start a maintenance window with:

```
sudo systemctl stop p4broker_1 p4d_1
sudo systemctl start p4broker_1_dfm
```

and end maintenance in the opposite order:

```
sudo systemctl stop p4broker_1_dfm
sudo systemctl start p4broker_1 p4d_1
```

Details may vary depending on what is occurring during maintenance.

Note SELinux fix ([Section 5.1.2.2, “Enabling systemd under SELinux”](#)) may be similarly required.

5.1.2.2. Enabling systemd under SELinux

If you have SELinux in **Enforcing** mode, then you may get an error message when you try and start the service:

```
$ systemctl start p4d_1
$ systemctl status p4d_1
:
Active: failed
Process: 1234 ExecStart=/p4/1/bin/p4d_1_init start (code=exited, status=203/EXEC)
:

$ journalctl -u p4d_1 --no-pager | tail
:
... p4d_1.service: Failed to execute command: Permission denied
... p4d_1.service: Failed at step EXEC spawning p4d_1_init: Permission denied
```

This can be easily fixed (as **root**):

```
semanage fcontext -a -t bin_t /p4/1/bin/p4d_1_init
restorecon -vF /p4/1/bin/p4d_1_init
```

If not already installed then **yum install policycoreutils-python-utils** gets you the basic commands mentioned above - you don't need the full **setools** which comes

with a GUI!

Then try again:

```
systemctl start p4d_1
systemctl status p4d_1
```

The status command should show **Active: active**

For troubleshooting SELinux, we recommend [the setroubleshoot utility](#)

Look for denied in /var/log/audit.log and then `ls -alZ <file>` for any file that triggered the denied message and go from there.

5.1.2.3. Configuring SysV Init Scripts

To configure services for an instance on systems using the SysV init mechanism, run these commands as the **root** user: Repeat this step for all instance init scripts you wish to configure as system services.

```
cd /etc/init.d
ln -s /p4/1/bin/p4d_1_init
chkconfig --add p4d_1_init
```

With that done, you can **start/stop/status** the service as **root** by running commands like:

```
service p4d_1_init status
service p4d_1_init start
service p4d_1_init stop
```

On SysV systems, you can also run the underlying init scripts directly as either the **root** or **perforce** user. If run as **root**, the script becomes **perforce** immediately, so that no processing occurs as root.

5.1.3. Configuring Automatic Service Start on Boot

You may want to configure your server machine such that the Helix Core Server for any given instance (and/or Proxy and/or Broker) will start automatically when the machine boots.

This is done using Systemd or Init scripts as covered below.

5.1.3.1. Automatic Start for Systems using systemd

Once systemd services are configured, you can enable the service to start on boot with a command like this, run as **root**:

```
systemctl enable p4d_1
```

The `enable` command configures the services to start automatically when the machine reboots, but does not immediately start the service. *Enabling services is optional*; you can start and stop the services manually regardless of whether it is enabled for automatic start on boot.

5.1.3.2. For systems using the SysV init mechanism

Once SysV services are configured, you can enable the service to start on boot with a command like this, run as `root`:

```
chkconfig p4d_1_init on
```

5.1.4. SDP Crontab Templates

The SDP includes basic crontab templates for master, replica, and edge servers in:

```
/p4/common/etc/cron.d
```

These define schedules for routine checkpoint operations, replica status checks, and email reviews.

5.1.5. Completing Your Server Configuration

1. Ensure that the admin user configured above has the correct password defined in `/p4/common/config/.p4passwd.p4_1.admin`, and then run the `p4login1` script (which calls the `p4 login` command using the `.p4passwd.p4_1.admin` file).
2. For new server instances, run this script, which sets several recommended configurables:

```
cd /p4/sdp/Server/setup/configure_new_server.sh 1
```

For existing servers, examine this file, and manually apply the `p4 configure` command to set configurables on your Perforce server instance.

Initialize the perforce user's crontab with one of these commands:

```
crontab /p4/p4.crontab
```

and customize execution times for the commands within the crontab files to suite the specific installation.

The SDP uses wrapper scripts in the crontab: `run_if_master.sh`, `run_if_edge.sh`, `run_if_replica.sh`. We suggest you ensure these are working as desired, e.g.

```
/p4/common/bin/run_if_master.sh 1 echo yes
/p4/common/bin/run_if_replica.sh 1 echo yes
/p4/common/bin/run_if_edge.sh 1 echo yes
```

The above should output **yes** if you are on the master (commit) machine (or replica/edge as appropriate), but otherwise nothing. Any issues with the above indicate incorrect values for **\$MASTER_ID**, or for other values within **/p4/common/config/p4_1.vars** (assuming instance **1**). You can debug this with:

```
bash -xv /p4/common/bin/run_if_master.sh 1 echo yes
```

If in doubt contact support.

5.1.6. Validating your SDP installation

Source your SDP environment variables and check that they look appropriate - for <instance> **1**:

```
source /p4/common/bin/p4_vars 1
```

The output of **p4 set** should be something like:

```
P4CONFIG=/p4/1/.p4config (config 'noconfig')
P4ENVIRO=/dev/null/.p4enviro
P4JOURNAL=/p4/1/logs/journal
P4LOG=/p4/1/logs/log
P4PCACHE=/p4/1/cache
P4PORT=ssl:1666
P4ROOT=/p4/1/root
P4SSLDIR=/p4/ssl
P4TICKETS=/p4/1/.p4tickets
P4TRUST=/p4/1/.p4trust
P4USER=perforce
```

There is a script **/p4/common/bin/verify_sdp.sh**. Run this specifying the <instance> id, e.g.

```
/p4/common/bin/verify_sdp.sh 1
```

The output should be something like:

```
verify_sdp.sh v5.6.1 Starting SDP verification on host helixcorevm1 at Fri 2020-08-14
17:02:45 UTC with this command line:
/p4/common/bin/verify_sdp.sh 1
```

If you have any questions about the output from this script, contact support-helix-core@perforce.com.

```

Finishing with:

```
Verifications completed, with 0 errors and 0 warnings detected in 57 checks.
```

If it mentions something like:

```
Verifications completed, with 2 errors and 1 warnings detected in 57 checks.
```

then review the details. If in doubt contact Perforce Support: support-helix-core@perforce.com

5.2. Local SDP Configuration

There are many scenarios where you may need to override a default value that the SDP provides. These changes must be done in specific locations so that your changes persist across SDP upgrades. There are two different scopes of configuration to be aware of and two locations you can place your configuration in:

Location	Scope	Description
/p4/common/site/config/\$P4SER VER.vars.local	SDP Instance Specific	Single configuration file that is scoped to a single SDP Instance
/p4/common/site/config/\$P4SER VER.vars.local.d/*	SDP Instance Specific	Directory of configuration files that are scoped to a single SDP Instance
/p4/common/site/config/p4_vars. local	SDP Wide	Single configuration file that is scoped to all SDP Instances

Location	Scope	Description
/p4/common/site/config/p4_vars.local.d/*	SDP Wide	Directory of configuration files that are scoped to all SDP Instances

5.2.1. Load Order

1. /p4/common/bin/p4_vars
2. /p4/common/site/config/p4_vars.local
3. /p4/common/site/config/p4_vars.local.d/*
4. /p4/common/config/\$P4SERVER.vars
5. /p4/common/site/config/\$P4SERVER.vars.local.d/*

5.3. Setting your login environment for convenience

Consider adding this to your `.bashrc` for the perforce user as a convenience for when you login:

```
echo "source /p4/common/bin/p4_vars 1" >> ~/.bashrc
```

Obviously if you have multiple instances on the same machine you might want to setup an alias or two to quickly switch between them.

5.4. Configuring protections, file types, monitoring and security

After the server instance is installed and configured, either with the Helix Installer or a manual installation, most sites will want to modify server permissions ("Protections") and security settings. Other common configuration steps include modifying the file type map and enabling process monitoring. To configure permissions, perform the following steps:

1. To set up protections, issue the `p4 protect` command. The protections table is displayed.
2. Delete the following line:

```
write user * * //depot/...
```

3. Define protections for your repository using groups. Perforce uses an inclusionary model. No access is given by default, you must specifically grant access to users/groups in the protections table. It is best for performance to grant users specific access to the areas of the depot that they need rather than granting everyone open access, and then trying to remove access via exclusionary mappings in the protect table even if that means you end up generating a larger protect table.
4. To set the default file types, run the `p4 typemap` command and define typemap entries to

override Perforce's default behavior.

5. Add any file type entries that are specific to your site. Suggestions:

- For already-compressed file types (such as `.zip`, `.gz`, `.avi`, `.gif`), assign a file type of `binary+Fl` to prevent p4d from attempting to compress them again before storing them.
- For regular binary files, add `binary+l` to make so that only one person at a time can check them out.

A sample file is provided in `$SDP/Server/config/typemap`

If you are doing things like games development with `Unreal Engine` or `Unity`, then there are specific recommended typemap to add in KB articles: [Search the Knowledge Base](#)

1. To make your changelists default to restricted (for high security environments):

```
p4 configure set defaultChangeType=restricted
```

5.5. Operating system configuration

Check [Chapter 8, Maximizing Server Performance](#) for detailed recommendations.

5.5.1. Configuring email for notifications

Use Postfix - which Integrates easily with Gmail, Office365 etc just search for postfix and the email provider. Examples:

- <https://www.howtoforge.com/tutorial/configure-postfix-to-use-gmail-as-a-mail-relay/>
- <https://support.google.com/accounts/answer/185833?hl=en#zippy=%2Cwhy-you-may-need-an-app-password>
- https://www.middlewareinventory.com/blog/postfix-relay-office-365/#3_Office_365_SMTp_relay_Discussed_in_this_Post

Please note that for Gmail:

- You must turn on 2FA for the account which is trying to create an app password
- The organization must allow 2FA (2-Step Verification) - this is normally turned off in Google Workspace (formerly known as G Suite).

Testing of email once configured:

```
echo "Test email" | mail -s "Test email subject" user@example.com
```

If there are problems sending email, then this may find the problem:

```
grep postfix /var/log/*
```

```
cat /var/log/maillog
```

5.5.2. Swarm Email Configuration

The advantage of installing Postfix is that it is easily testable from the command line as above.

The Swarm configuration then becomes editing `config.php` as below (optional sender address) and restarting Swarm in the normal way (resetting its cache first):

```
// this block should be a peer of 'p4'
'mail' => array(
    // 'sender' => 'swarm@my.domain', // defaults to 'notifications@hostname'
    'transport' => array(
        'name' => 'localhost', // name of SMTP host
        'host' => 'localhost', // host/IP of SMTP host
    ),
),
),
```

Restarting Swarm (on CentOS):

```
cd /opt/perforce/swarm/data
rm cache/*cache.php
systemctl restart httpd
```

5.5.3. Configuring PagerDuty for notifications

The default behavior of the SDP is to use email for delivering alerts and log files. This section details replacing email with [PagerDuty](#).

5.5.3.1. Prerequisites

- [PagerDuty Account](#)
- [PagerDuty Service](#) where SDP/Helix Core incidents will be created
- Events API V2 Integration added to PagerDuty Service, this will produce an Integration Key which will be used later
- [Install PagerDuty CLI](#)

5.5.3.2. SDP Configuration

The following can be added to `/p4/common/site/config/p4_vars.local` to configure the SDP to use PagerDuty:

```
# set this environment variable to the Integration Key that was created when adding
the
```

```
# Events API V2 Integration to your PagerDuty Service
export PAGERDUTY_ROUTING_KEY="2ac2....e5c3"
```

5.5.3.3. Optional variables

The SDP will automatically set the Title of the PagerDuty Incident based on the exception that occurred. The SDP will also include the log file from the exception (example: checkpoint log, p4verify log, etc).

If you have multiple Helix Core servers it will be helpful to include some additional context with the incident so you know which server the alert is coming from.

The following environment variable can optionally be used to add additional context to the PagerDuty Incident:

```
# export PAGERDUTY_CUSTOM_FIELD=""
```

Example Additional Context Configuration

The following snippet will create environment variables in `p4_vars.local` that will provide additional context in each PagerDuty Incident:

```
curl -s -H Metadata:true --noproxy "*" "http://169.254.169.254/metadata/instance?api-
version=2021-02-01" > /tmp/azure_metadata
cat <<-EOF >> /p4/common/site/config/p4_vars.local
export PAGERDUTY_ROUTING_KEY="2ac2....e5c3"
export VM_ID="$(jq -r '.compute.vmId' /tmp/azure_metadata)"
export REGION="$(jq -r '.compute.location' /tmp/azure_metadata)"
export AZURE_SUBSCRIPTION_ID="$(jq -r '.compute.subscriptionId' /tmp/azure_metadata)"
export PAGERDUTY_CUSTOM_FIELD=$(cat <<-END
#####
Azure Subscription: \${AZURE_SUBSCRIPTION_ID}
Region: \${REGION}
Azure VM ID: \${VM_ID}
#####
END
)
EOF
```

The following context will be added as a field on the PagerDuty Incident:

```
#####
Azure Subscription: f306878d-d321-4731-4cd3-f3afafbbd3ac
Region: eastus
Azure VM ID: 5ee13bfe-8a0c-486f-ae08-c43e44255d15
#####
```

5.5.4. Configuring AWS Simple Notification Service (SNS) for notifications

The default behavior of the SDP is to use email for delivering alerts and log files. This section details replacing email with AWS SNS.

5.5.4.1. Prerequisites

- AWS CLI installed
- Authorization for `publish` to a AWS SNS topic

5.5.4.2. SDP Configuration

The following can be added to `/p4/common/config/p4_1.vars` to configure the SDP to use SNS:

```
# SNS Alert Configurations
# Two methods of authentication are supported: key pair (on prem, azure, etc) and IAM
role (AWS deployment)
# In the case of IAM role the AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY environment
variables must not be set, not even empty strings
```

```
# To test SNS delivery use the following command: aws sns publish --topic-arn
${SNS_ALERT_TOPIC_ARN} --subject test --message "this is a test"
```

```
# export AWS_ACCESS_KEY_ID=""
# export AWS_SECRET_ACCESS_KEY=""
```

```
export AWS_DEFAULT_REGION="us-east-1"
export SNS_ALERT_TOPIC_ARN="arn:aws:sns:us-east-1:541621974560:Perforce-Notifications-
SnsTopic-1FIRH0KEAXTU"
```

5.5.4.3. Example IAM Policy

The following is an example policy that could be used for either an IAM Role or an IAM user with key/secret:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "sns:Publish",
      "Resource": "arn:aws:sns:us-east-1:541621974560:Perforce-Notifications-*",
      "Effect": "Allow"
    }
  ]
}
```

```
}
```

5.6. Other server configurables

There are various configurables that you should consider setting for your server instance.

Some suggestions are in the file: `$SDP/Server/setup/configure_new_server.sh`

Review the contents and either apply individual settings manually, or edit the file and apply the newly edited version. If you have any questions, please see the [configurables section in Command Reference Guide appendix](#) (get the right version for your server!). You can also contact support regarding questions.

5.7. Archiving configuration files

Now that the server instance is running properly, copy the following configuration files to the `hxdepots` volume for backup:

- Any init scripts used in `/etc/init.d` or any systemd scripts to `/etc/systemd/system`
- A copy of the crontab file, obtained using `crontab -l`.
- Any other relevant configuration scripts, such as cluster configuration scripts, failover scripts, or disk failover configuration files.

5.8. Installing Swarm Triggers

On the commit server (**NOT** the Swarm machine), get it setup to connect to the Perforce package repo (if not already done). See: <https://www.perforce.com/perforce-packages>

Install the trigger package, e.g.:

- `yum install helix-swarm-triggers` (if Red Hat family, i.e. RHEL, Rocky Linux, CentOS, Amazon Linux).
- `apt install helix-swarm-triggers` (for Ubuntu)

Then (for SDP environments for ease):

```
sudo chown -R perforce:perforce /opt/perforce/etc
```

Then install the triggers on the p4d server. Something like:

```
vi /opt/perforce/etc/swarm-triggers.conf
```

Make it look something like (in SDP env):

```

SWARM_HOST='https://swarm.p4.p4bsw.com'
SWARM_TOKEN='MY-UUID-STYLE-TOKEN'
ADMIN_USER='swarm'
ADMIN_TICKET_FILE='/p4/1/.p4tickets'
P4_PORT='ssl:1666'
P4='/p4/1/bin/p4_1'
EXEMPT_FILE_COUNT=0
EXEMPT_EXTENSIONS=''
VERIFY_SSL=1
TIMEOUT=30
IGNORE_TIMEOUT=1
IGNORE_NOSERVER=1

```

Then test that config file:

```

chmod +x /p4/sdp/Unsupported/setup/swarm_triggers_test.sh
/p4/sdp/Unsupported/setup/swarm_triggers_test.sh

```

Get that to be happy. May require iteration of the conf file, trigger install, etc.

Then install triggers on the server.

```

cd /p4/1/tmp
p4 triggers -o > temp_file.txt

/opt/perforce/swarm-triggers/bin/swarm-trigger.pl -o >> tmp_file.txt

vi tmp_file.txt # Clean up formatting, make it syntactically correct.

p4 triggers -i < temp_file.txt
p4 triggers -o # Make sure it's there.

```

Then test!

```

mkdir /p4/1/tmp/swarm_test
cd /p4/1/tmp/swarm_test

export P4CONFIG=.p4config
echo P4CLIENT=swarm_test.$(hostname -s)>>.p4config

# Make a workspace, map View to some location where we can edit harmlessly,
# or use a stream like //sandbox/main
p4 client

p4 add chg.txt

# The important thing is '#review' which trigger will process

```

```
p4 change -o | sed 's:<enter description here>:#review' > chg.txt
```

```
p4 change -i < chg.txt
```

```
p4 shelve -c CL # Use CL listed in output from prior command
```

```
p4 describe -s CL # if #review gets replace by something like #review-12345, you're Done!
```

Chapter 6. Backup, Replication, and Recovery

Perforce server instances maintain *metadata* and *versioned files*. The metadata contains all the information about the files in the depots. Metadata resides in database (db.*) files in the server instance's root directory (P4ROOT). The versioned files contain the file changes that have been submitted to the repository. Versioned files reside on the hxdepots volume.

This section assumes that you understand the basics of Perforce backup and recovery. For more information, consult the Perforce [System Administrator's Guide](#) and [failover](#).

6.1. Typical Backup Procedure

The SDP's maintenance scripts, run as `cron` tasks, periodically back up the metadata. The weekly sequence is described below.

Seven nights a week, perform the following tasks:

1. Truncate the active journal.
2. Replay the journal to the offline database. (Refer to Figure 2: SDP Runtime Structure and Volume Layout for more information on the location of the live and offline databases.)
3. Create a checkpoint from the offline database.
4. Recreate the offline database from the last checkpoint.

Once a week, perform the following tasks:

1. Verify all depot files.

Once every few months, perform the following tasks:

1. Stop the live server instance.
2. Truncate the active journal.
3. Replay the journal to the offline database. (Refer to Figure 2: SDP Runtime Structure and Volume Layout for more information on the location of the live and offline databases.)
4. Archive the live database.
5. Move the offline database to the live database directory.
6. Start the live server instance.
7. Create a new checkpoint from the archive of the live database.
8. Recreate the offline database from the last checkpoint.
9. Verify all depots.

This normal maintenance procedure puts the checkpoints (metadata snapshots) on the hxdepots volume, which contains the versioned files. Backing up the hxdepots volume with a normal backup utility like `rsync` preserves the critical assets necessary for recovery.

To ensure that the backup does not interfere with the metadata backups (checkpoints), coordinate backup of the hxdepots volume using the SDP maintenance scripts.

The preceding maintenance procedure minimizes service outage, because checkpoints are created from offline or saved databases while the live p4d server process is running on the live databases in P4ROOT.

With no additional configuration, the normal maintenance prevents loss of more than one day's metadata changes. To provide an optimal [Recovery Point Objective](#) (RPO), the SDP provides additional tools for replication.

6.2. Planning for HA and DR

The concepts for HA (High Availability) and DR (Disaster Recovery) are fairly similar - they are both types of Helix Core replica.

When you have server specs with `Services` field set to `commit-server`, `standard`, or `edge-server` - see [deployment architectures](#) you should consider your requirements for how to recover from a failure to any such servers.

See also [Replica types and use cases](#)

The key issues are around ensuring that you have appropriate values for the following measures for your Helix Core installation:

- RTO - Recovery Time Objective - how long will it take you to recover to a backup?
- RPO - Recovery Point Objective - how much data are you prepared to risk losing if you have to failover to a backup server?

We need to consider planned vs unplanned failover. Planned may be due to upgrading the core Operating System or some other dependency in your infrastructure, or a similar activity.

Unplanned covers risks you are seeking to mitigate with failover:

- loss of a machine, or some machine related hardware failure (e.g. network)
- loss of a VM cluster
- failure of storage
- loss of a data center or machine room
- etc...

So, if your main `commit-server` fails, how fast should you be able to be up and running again, and how much data might you be prepared to lose? What is the potential disruption to your organization if the Helix Core repository is down? How many people would be impacted in some way?

You also need to consider the costs of your mitigation strategies. For example, this can range from:

- taking a backup once per 24 hours and requiring maybe an hour or two to restore it. Thus you

might lose up to 24 hours of work for an unplanned failure, and require several hours to restore.

- having a high availability replica which is a mirror of the server hardware and ready to take over within minutes if required

Having a replica for HA or DR is likely to reduce your RPO and RTO to well under an hour (<10 minutes if properly prepared for) - at the cost of the resources to run such a replica, and the management overhead to monitor it appropriately.

Typically we would define:

- An HA replica is close to its upstream server, e.g. in the same Data Center - this minimizes the latency for replication, and reduces RPO
- A DR replica is in a more remote location, so maybe risks being further behind in replication (thus higher RPO), but mitigates against catastrophic loss of a data center or similar. Note that "further behind" is still typically seconds for metadata, but can be minutes for submits with many GB of files.

6.2.1. Further Resources

- [High Reliability Solutions](#)

6.2.2. Creating a Failover Replica for Commit or Edge Server

A commit server instance is the ultimate store for submitted data, and also for any workspace state (WIP - work in progress) for users directly working with the commit server (part of the same "data set")

An edge server instance maintains its own copy of workspace state (WIP). If you have people connecting to an edge server, then any workspaces they create (and files they open for some action) will be only stored on the edge server. Thus it is normally recommended to have an HA backup server, so that users don't lose their state in case of failover.

There is a concept of a "build edge" which is an edge server which only supports build farm users. In this scenario it may be deemed acceptable to not have an HA backup server, since in the case of failure of the edge, it can be re-seeded from the commit server. All build farm clients would be recreated from scratch so there would be no problems.

6.2.3. What is a Failover Replica?

A Failover is the hand off of the role of a master/primary/commit server from a primary server machine to a standby replica (typically on a different server machine). As part of failover processing the secondary/backup is promoted to become the new master/primary/commit server.

As of 2018.2 release, p4d supports a `p4 failover` command that performs a failover to a `standby` replica (i.e. a replica with `Services:` field value set to `standby` or `forwarding-standby`). Such a replica performs a `journalcopy` replication of metadata, with a local pull thread to update its `db.*` files. After the failover is complete, traffic must be redirected to the server machine where newly promoted standby server operates, e.g. with a DNS change (possibly automated with a post-failover

trigger).

See also: [Configuring a Helix Core Standby](#).

On Linux the SDP script `mkrep.sh` greatly simplifies the process of setting up a replica suitable for use with the `p4 failover` command. See: [Section 6.3.4, “Using mkrep.sh”](#).

6.2.4. Mandatory vs Non-mandatory Standbys

You can modify the `Options:` field of the server spec of a `standby` or `forwarding-standby` replica to make it `mandatory`. This setting affects the mechanics of how failover works.

When a `standby` server instance is configured as mandatory, the master/commit server will wait until this server confirms it has processed journal data before allowing that journal data to be released to other replicas. This can simplify failover if the master server is unavailable to participate in the failover, since it provides a guarantee that no downstream servers are **ahead** of the replica.

This guarantee is important, as it ensures downstream servers can simply be re-directed to point to the standby after the master server has failed over to its standby, and will carry on working without problems or need for human intervention on the servers.

Failovers in which the master does not participate are generally referred to as *unscheduled* or *reactive*, and are generally done in response to an unexpected situation. Failovers in which the master server is alive and well at the start of processing, and in which the master server participates in the failover, are referred to as *scheduled* or *planned*.

If a server which is marked as `mandatory` goes offline for any reason, the replication to other replicas will stop replicating. In this scenario, the server spec of the replica can be changed to `nomandatory`, and then replication will immediately resume, so long as the replication has not been offline for so long that the master server has removed numbered journals that would be needed to catch up (typically several days or weeks depending on the `KEEPJNLS` setting). If this happens, the `p4d` server logs of all impacted servers will clearly indicate the root cause, so long `p4d` versions are 2019.2 or later.

If set to `nomandatory` then there is no risk of delaying downstream replicas, however there is no guarantee that they will be able to switch seamlessly over to the new server in event of an unscheduled failover.

We recommend creating `mandatory` standby replica(s) if the server is local to its commit server. We also recommend active monitoring in place to quickly detect replication lag or other issues.

To change a server spec to be `mandatory` or `nomandatory`, modify the server spec with a command like `p4 server p4d_ha_bos` to edit the form, and then change the value in the `Options:` field to be as desired, `mandatory` or `nomandatory`, and the save and exit the editor.

6.2.5. Server host naming conventions

This is recommended, but not a requirement for SDP scripts to implement failover.

- Use a name that does not indicate switchable roles, e.g. don't indicate in the name whether a host is a master/primary or backup, or edge server and its backup. This might otherwise lead to confusion once you have performed a failover and the host name is no longer appropriate.
- Use names ending numeric designators, e.g. -01 or -05. The goal is to avoid being in a post-failover situation where a machine with **master** or **primary** is actually the backup. Also, the assumption is that host names will never need to change.
- While you don't want switchable roles baked into the hostname, you can have static roles, e.g. use p4d vs. p4p in the host name (as those generally don't change). The p4d could be primary, standby, edge, edge's standby (switchable roles).
- Using a short geographic site is sometimes helpful/desirable. If used, use the same site tag used in the ServerID, e.g. aus.

Valid site tags should be listed in: `/p4/common/config/SiteTags.cfg` - see [Section 6.3.4.1, "SiteTags.cfg"](#)

- Using a short tag to indicate the major OS version is **sometimes** helpful/desirable, eg. c7 for CentOS 7, or r8 for RHEL 8. This is based on the idea that when the major OS is upgraded, you either move to new hardware, or change the host name (an exception to the rule above about never changing the hostname). This option maybe overkill for many sites.
- End users should reference a DNS name that may include the site tag, but would exclude the number, OS indicator, and server type (p4d/p4p/p4broker), replacing all that with just **perforce** or optionally just **p4**. General idea is that users needn't be bothered by under-the-covers tech of whether something is a proxy or replica.
- For edge servers, it is advisable to include **edge** in both the host and DNS name, as users and admins needs to be aware of the functional differences due to a server being an edge server.

Examples:

- **p4d-aus-r7-03**, a master in Austin on RHEL 7, pointed to by a DNS name like **p4-aus**.
- **p4d-aus-03**, a master in Austin (no indication of server OS), pointed to by a DNS name like **p4-aus**.
- **p4d-aus-r7-04**, a standby replica in Austin on RHEL 7, not pointed to by a DNS until failover, at which point it gets pointed to by **p4-aus**.
- **p4p-syd-r8-05**, a proxy in Sydney on RHEL 8, pointed to by a DNS name like **p4-syd**.
- **p4d-syd-r8-04**, a replica that replaced the proxy in Sydney, on RHEL 8, pointed to by a DNS name like **p4-syd** (same as the proxy it replaced).
- **p4d-edge-tok-s12-03**, an edge in Tokyo running SuSE12, pointed to by a DNS name like **p4edge-tok**.
- **p4d-edge-tok-s12-04**, a replica of an edge in Tokyo running SuSE12, not pointed to by a DNS name until failover, at which point it gets pointed to by **p4edge-tok**.

FQDNs (fully qualified DNS names) of short DNS names used in these examples would also exist, and would be based on the same short names.

6.3. Full One-Way Replication

Perforce supports a full one-way [replication](#) of data from a master server to a replica, including versioned files. The `p4 pull` command is the replication mechanism, and a replica server can be configured to know it is a replica and use the replication command. The `p4 pull` mechanism requires very little configuration and no additional scripting. As this replication mechanism is simple and effective, we recommend it as the preferred replication technique. Replica servers can also be configured to only contain metadata, which can be useful for reporting or offline checkpointing purposes. See the [Distributing Perforce Guide](#) for details on setting up replica servers.

If you wish to use the replica as a read-only server, you can use the [P4Broker](#) to direct read-only commands to the replica or you can use a forwarding replica. The broker can do load balancing to a pool of replicas if you need more than one replica to handle your load.

6.3.1. Replication Setup

To configure a replica server, first configure a machine identically to the master server (at least as regards the link structure such as `/p4`, `/p4/common/bin` and `/p4/instance/*`), then install the SDP on it to match the master server installation. Once the machine and SDP install is in place, you need to configure the master server for replication.

Perforce supports many types of replicas suited to a variety of purposes, such as:

- Real-time backup,
- Providing a disaster recovery solution,
- Load distribution to enhance performance,
- Distributed development,
- Dedicated resources for automated systems, such as build servers, and more.

We always recommend first setting up the replica as a read-only replica and ensuring that everything is working. Once that is the case you can easily modify server specs and configurables to change it to a forwarding replica, or an edge server etc.

6.3.2. Replication Setup for Failover

This is just a special case of replication, but implementing [Section 6.2.3, “What is a Failover Replica?”](#)

Please note the section below [Section 6.3.4, “Using `mkrep.sh`”](#) which implements many details.

6.3.3. Pre-requisites for Failover

These are vital as part of your planning.

- Obtain and install a license for your replica(s)

Your commit or standard server has a license file (tied to IP address), while your replicas do not require one to function as replicas.

However, in order for a replica to function as a replacement for a commit or standard server, it must have a suitable license installed.

This should be requested when the replica is first created. See the form: <https://www.perforce.com/support/duplicate-server-request>

- Review your authentication mechanism (LDAP etc) - is the LDAP server contactable from the replica machine (firewalls etc configured appropriately).
- Review all your triggers and how they are deployed - will they work on the failover host?

Is the right version of Perl/Python etc correctly installed and configured on the failover host with all imported libraries?

TEST, TEST, TEST!!! It is important to test the above issues as part of your planning. For peace of mind you don't want to be finding problems at the time of trying to failover for real, which may be in the middle of the night!

On Linux:

- Review the configuration of options such as [Section 8.1, “Ensure Transparent Huge Pages \(THP\) is turned off”](#) and also [Section 8.2, “Putting server.locks directory into RAM”](#) are correctly configured for your HA server machine - otherwise you **risk reduced performance** after failover.

6.3.4. Using mkrep.sh

The SDP `mkrep.sh` script should be used to expand your Helix Topology, e.g. adding replicas and edge servers. For the detailed usage statement, go to [Section 9.4.7, “mkrep.sh”](#)

When creating server machines to be used as Helix servers, the server machines should be named following a well-designed host naming convention. The SDP has no dependency on the convention used, and so any existing local naming convention can be applied. The SDP includes a suggested naming convention in [Section 6.2.5, “Server host naming conventions”](#)

6.3.4.1. SiteTags.cfg

The `mkrep.sh` documentation references a `SiteTags.cfg` file used to register short tag names for geographic sites. Location is: `/p4/common/config/SiteTags.cfg`

Your tags should use abbreviations that are meaningful to your organization.

Example/Format

```
# Valid Geographic site tags.

# Each is intended to indicate a geography, and optionally a specific Data
# Center (or Computer Room, or Computer Closet) within a given geographic
# location.
#
# The format is:
# Name: Description
# The Name must be alphanumeric only. The Description may contain spaces.
# Lines starting with # and blank lines are ignored.

```

A sample file exists `/p4/common/config/SiteTags.cfg.sample`.

6.3.4.2. Output of `mkrep.sh`

The output of `mkrep.sh` (which is also written to a log file in `/p4/<instance>/logs/mkrep.*`) describes a number of steps required to continue setting up the replica after the metadata configuration performed by the script is done.

6.3.5. Addition Replication Setup

In addition to steps recommended by `mkrep.sh`, there are other steps to be aware of to prepare a replica server machine.

6.3.6. SDP Installation

The SDP must first be installed on the replica server machine. If SDP already exists on the machine but not for the current instance, then `mkdirs.sh` must be used to add a new instance to the machine.

6.3.6.1. SSH Key Setup

SSH keys for the `perforce` operating system user should be setup to allow the `perforce` user to `ssh` and `rsync` among the Helix server machines in the topology. If no `~perforce/.ssh` directory exist on a machine, it can be created with this command:

```
ssh-keygen -t rsa -b 4096
```

6.4. Recovery Procedures

There are three scenarios that require you to recover server data:

Metadata	Depotdata	Action required
lost or corrupt	Intact	Recover metadata as described below
Intact	lost or corrupt	Call Perforce Support
lost or corrupt	lost or corrupt	Recover metadata as described below. Recover the hxdepots volume using your normal backup utilities.

Restoring the metadata from a backup also optimizes the database files.

6.4.1. Recovering a master server from a checkpoint and journal(s)

The checkpoint files are stored in the `/p4/instance/checkpoints` directory, and the most recent checkpoint is named `p4_instance.ckp.number.gz`. Recreating up-to-date database files requires the most recent checkpoint, from `/p4/instance/checkpoints` and the journal file from `/p4/instance/logs`.

To recover the server database manually, perform the following steps from the root directory of the server (`/p4/instance/root`).

Assuming instance 1:

1. Stop the Perforce Server by issuing the following command:

```
/p4/1/bin/p4_1 admin stop
```

2. Delete the old database files in the `/p4/1/root/save` directory
3. Move the live database files (db.*) to the save directory.
4. Use the following command to restore from the most recent checkpoint.

```
/p4/1/bin/p4d_1 -r /p4/1/root -jr -z /p4/1/checkpoints/p4_1.ckp.####.gz
```

5. To replay the transactions that occurred after the checkpoint was created, issue the following command:

```
/p4/1/bin/p4d_1 -r /p4/1/root -jr /p4/1/logs/journal
```

6. Restart your Perforce server.

If the Perforce service starts without errors, delete the old database files from `/p4/instance/root/save`.

If problems are reported when you attempt to recover from the most recent checkpoint, try recovering from the preceding checkpoint and journal. If you are successful, replay the subsequent journal. If the journals are corrupted, contact [Perforce Technical Support](#). For full details about backup and recovery, refer to the [Perforce System Administrator's Guide](#).

6.4.2. Recovering a replica from a checkpoint

This is very similar to creating a replica in the first place as described above.

If you have been running the replica crontab commands as suggested, then you will have the latest checkpoints from the master already copied across to the replica through the use of [Section 9.6.33](#), “`sync_replica.sh`”.

See the steps in the script [Section 9.6.33](#), “`sync_replica.sh`” for details (note that it deletes the state and `rdb.lbr` files from the replica root directory so that the replica starts replicating from the start of a journal).

Remember to ensure you have logged the service user in to the master server (and that the ticket is stored in the correct location as described when setting up the replica).

6.4.3. Recovering from a tape backup

This section describes how to recover from a tape or other offline backup to a new server machine if the server machine fails. The tape backup for the server is made from the `hxdepots` volume. The new server machine must have the same volume layout and user/group settings as the original server. In other words, the new server must be as identical as possible to the server that failed.

To recover from a tape backup, perform the following steps (assuming instance 1):

1. Recover the `hxdepots` volume from your backup tape.
2. Create the `/p4` convenience directory on the OS volume.
3. Create the directories `/hxmetadata/p4/1/db1/save` and `/hxmetadata/p4/1/offline_db`.
4. Create the directories `/hxmetadata/p4/1/db2/save` and `/hxmetadata/p4/2/offline_db`.
5. Change ownership of these directories to the OS account that runs the Perforce processes.
6. Switch to the Perforce OS account, and create a link in the `/p4` directory to `/hxdepots/p4/1`.
7. Create a link in the `/p4` directory to `/hxdepots/p4/common`.
8. As a super-user, reinstall and enable the Systemd service files or or SysV init scripts.
9. Find the last available checkpoint, under `/p4/1/checkpoints`

10. Recover the latest checkpoint by running:

```
/p4/1/bin/p4d_1 -r /p4/1/root -jr -z <last_ckpt_file>
```

11. Recover the checkpoint to the `offline_db` directory (assuming instance 1):

```
/p4/1/bin/p4d_1 -r /p4/1/offline_db -jr -z <last_ckpt_file>
```

12. Reinstall the Perforce server license to the server root directory.

13. Start the perforce service by running `/p4/1/bin/p4d_1_init start``

14. Verify that the server instance is running.

15. Reinstall the server crontab or scheduled tasks.

16. Perform any other initial server machine configuration.

17. Verify the database and versioned files by running the `p4verify.sh` script. Note that files using the `+k` file type modifier might be reported as BAD! after being moved. Contact Perforce Technical Support for assistance in determining if these files are actually corrupt.

6.4.4. Failover to a replicated standby machine

See [SDP Failover Guide \(PDF\)](#) or [SDP Failover Guide \(HTML\)](#) for detailed steps.

Chapter 7. Upgrades

This section describes both upgrades of the SDP itself, as well as upgrades of Helix software such as p4d, p4broker, p4p, and the the p4 command line client in the SDP structure.

7.1. Upgrade Order: SDP first, then Helix P4D

The SDP should normally be upgraded prior to the upgrade of Helix Core (P4D). If you are upgrading P4D to or beyond P4D 2019.1 from a prior version of P4D, you *must* upgrade the SDP first. If you run multiple instances of P4D on a given machine (potentially each running different versions of P4D), upgrade the SDP first before upgrading any of the instances.

The SDP should also be upgraded before upgrading other Helix software on machines using the SDP, including p4d, p4p, p4broker, and p4 (the command line client).

Upgrading a Helix Core server instance in the SDP framework is a simple process involving a few steps.

7.2. SDP and P4D Version Compatibility

Starting with the SDP 2020.1 release, the released versions of SDP match the released versions of P4D. So SDP r20.1 is guaranteed to work with P4D r20.1. In addition, the [SDP Release Notes](#) clarify all the specific versions of P4D supported.

The SDP is often forward- and backward-compatible with P4D versions, but for best results they should be kept in sync by upgrading SDP before P4D. This is partly because the SDP contains logic that helps upgrade P4D, which can change as P4D evolves (most recently for 2019.1).

The SDP is aware of the P4D version, and has backward-compatibility logic to support older versions of P4D. This is guaranteed for supported versions of P4D. Backward compatibility of SDP with older versions of P4D may extend farther back, though without the "officially supported" guarantee.

7.3. Upgrading the SDP

Starting with this SDP 2021.1 release, upgrades of the SDP from 2020.1 and later use a new mechanism. The SDP upgrade procedure starting from 2020.1 and later uses the `sdp_upgrade.sh` script. Some highlights of the new upgrade mechanism:

- **Automated:** Upgrades from SDP 2020.1 are automated with `sdp_upgrade.sh` provided with each new version of the SDP.
- **Continuous:** Each new SDP version, starting from SDP 2021.1, will maintain the capability to upgrade from all prior versions, so long as the starting version is SDP 2020.1 or later.
- **Independent:** SDP upgrades will enable upgrades to new Helix Core versions, but will not directly cause Helix Core upgrades to occur immediately. Each Helix Core instance can be upgraded independently of the SDP on its own schedule.

7.3.1. Sample SDP Upgrade Procedure

For complete information, see: [Section 9.2.3, “sdp_upgrade.sh”](#).

A basic set of commands is:

```
cd /hxdepots
[[ -d downloads ]] || mkdir downloads
cd downloads
[[ -d new ]] && mv new old.$(date +%Y%m%d-%H%M%S')
[[ -e sdp.Unix.tgz ]] && mv sdp.Unix.tgz sdp.Unix.old.$(date +%Y%m%d-%H%M%S')
curl -L -s -O https://swarm.workshop.perforce.com/projects/perforce-software-
sdp/download/downloads/sdp.Unix.tgz
ls -l sdp.Unix.tgz
mkdir new
cd new
tar -xzf ../sdp.Unix.tgz
```

After extracting the SDP tarball, cd to the directory where the `sdp_upgrade.sh` script resides, and execute it from there:

```
cd /hxdepots/downloads/new/sdp/Server/Unix/p4/common/sdp_upgrade
./sdp_upgrade.sh -man
```

If the `curl` command cannot be used (perhaps due to lack of outbound internet access), replace that step with some other means of acquiring the SDP tarball such that it lands as `/hxdepots/downloads/sdp.Unix.tgz`, and then proceed from that point forward.

What if there is no `/hxdepots` ?

If the existing SDP does not have a `/hxdepots` directory, find the correct value with this command:

```
bash -c 'cd /p4/common; d=$(pwd -P); echo ${d%/p4/common}'
```

This can be run from any shell (bash, tcsh, zsh, etc.)

7.3.2. SDP Legacy Upgrade Procedure

If your current SDP is older than the 2020.1 release, see the [SDP Legacy Upgrade Guide \(for Unix\)](#) for information on upgrading SDP to SDP 2020.1 from any prior version (dating back to 2007).

7.4. Upgrading Helix Software with the SDP

The following outlines the procedure for upgrading Helix binaries using the SDP scripts.

7.4.1. Get Latest Helix Binaries

Acquire the latest Perforce Helix binaries to stage them for upgrade using the [Section 9.2.1](#), “`get_helix_binaries.sh`” script.

If you have multiple server machines with SDP, staging can be done with this script on one machine first, and then the `/hxdepots/sdp/helix_binaries` folder can be rsync'd to other machines.

Alternately, this script can be run on each machine, but as patches can be released at any time, running it once and then distributing the `helix_binaries` directory internally via rsync is preferred to ensure all machines at your site deploy with the same binary versions.

See [Section 9.2.1](#), “`get_helix_binaries.sh`”

7.4.2. Upgrade Each Instance

Use the SDP `upgrade.sh` script to upgrade each instance of Helix on the current machine, using the staged binaries. The upgrade process handles all aspects of upgrading, including adjusting the database structure, executing commands to upgrade the p4d database schema, and managing the SDP symlinks in `/p4/common/bin`.

Instances can be upgraded independently of each other.

See [Section 9.2.2](#), “`upgrade.sh`”.

7.4.3. Global Topology Upgrades - Outer to Inner

For any given instance, be aware of the Helix topology when performing upgrades, specifically whether that instance has replicas and/or edge servers. When replicas and edge servers exist (and are active), the order in which `upgrade.sh` must be run on different server machines matters. Perform upgrades following an “outer to inner” strategy.

For example, say for SDP instance 1, your site has the following server machines:

- bos-helix-01 - The master (in Boston, USA)
- bos-helix-02 - Replica of master (in Boston, USA)
- nyc-helix-03 - Replica of master (in New York, USA)
- syd-helix-04 - Edge Server (in Sydney, AU)
- syd-helix-05 - Replica of Sydney edge (in Sydney)

Envision the above topology with the master server in the center, and two concentric circles.

The Replica of the Sydney edge would be done first, as it is by itself in the outermost circle.

The Edge server and two Replicas of the master are all at the next inner circle. So bos-helix-02, nyc-

helix-03, and syd-helix-04 could be upgraded in any order with respect to each other, or even simultaneously, as they are in the same circle.

The master is the innermost, and would be upgraded last.

A few standards need to be in place to make this super easy:

- The `perforce` operating system user would have properly configured SSH keys to allow passwordless ssh from the master to all other servers.
- The `perforce` user shell environment (`~/.bash_profile` and `~/.bashrc`) ensured that the SDP shell environment automatically sourced

The Helix global topology upgrade could be done something like, starting as `perforce@bos-helix-01`:

```
cd /p4/sdp/helix_binaries
./get_helix_binaries.sh
rsync -a /p4/sdp/helix_binaries/ syd-helix-05:/p4/sdp/helix_binaries
rsync -a /p4/sdp/helix_binaries/ syd-helix-04:/p4/sdp/helix_binaries
rsync -a /p4/sdp/helix_binaries/ nyc-helix-03:/p4/sdp/helix_binaries
rsync -a /p4/sdp/helix_binaries/ bos-helix-02:/p4/sdp/helix_binaries
```

Then do a preview of the upgrade on all machines, in outer-to-inner order:

```
ssh syd-helix-05 upgrade.sh
ssh syd-helix-04 upgrade.sh
ssh nyc-helix-03 upgrade.sh
ssh bos-helix-02 upgrade.sh
ssh bos-helix-01 upgrade.sh
```

On each machine, check for a message in the output that contains `Success: Finished`. If that looks good, then proceed to execute the actual upgrades:

```
ssh syd-helix-05 upgrade.sh -y
ssh syd-helix-04 upgrade.sh -y
ssh nyc-helix-03 upgrade.sh -y
ssh bos-helix-02 upgrade.sh -y
ssh bos-helix-01 upgrade.sh -y
```

As with the preview, check for a message in the output that contains `Success: Finished`.

7.5. Database Modifications

Occasionally modifications are made to the Perforce database from one release to another. For example, server upgrades and some recovery procedures modify the database.

When upgrading the server, replaying a journal patch, or performing any activity that modifies the

db.* files, you must ensure that the offline checkpoint process is functioning correctly so that the files in the `offline_db` directory match the ones in the live server directory.

Normally upgrades to the `offline_db` after a P4D upgrade will be applied by rotating the journal in the normal way, and applying it to the `offline_db`.

In some cases it is necessary to restart the offline checkpoint process and the easiest way to is to run the `live_checkpoint` script after modifying the `db.*` files, as follows:

```
/p4/common/bin/live_checkpoint.sh 1
```

This script makes a new checkpoint of the modified database files in the live `root` directory, then recovers that checkpoint to the `offline_db` directory so that both directories are in sync. This script can also be used anytime to create a checkpoint of the live database.

Please note the warnings about how long this process may take at [Section 9.4.6](#), “`live_checkpoint.sh`”

This command should be run when an error occurs during offline checkpointing. It restarts the offline checkpoint process from the live database files to bring the offline copy back in sync. If the live checkpoint script fails, contact Perforce Consulting at consulting@perforce.com.

Chapter 8. Maximizing Server Performance

The following sections provide some guidelines for maximizing the performance of the Perforce Helix Core Server, using tools provided by the SDP. More information on this topic can be found in the [Knowledge Base](#).

8.1. Ensure Transparent Huge Pages (THP) is turned off

This is reference [KB Article on Platform Notes](#)

There is a (now deprecated) script in the SDP which will do this:

```
/p4/sdp/Server/Unix/setup/os_tweaks.sh
```

It needs to be run as **root** or using **sudo**. This will not persist after system is rebooted - and is thus no longer the recommended option.

We recommend the usage of **tuned** instead of the above, since it will persist after reboots.

Install as appropriate for your Linux distribution (so as **root**):

```
yum install tuned
```

or

```
apt-get install tuned
```

1. Create a customized **tuned** profile with disabled THP. Create a new directory in **/etc/tuned** directory with desired profile name:

```
mkdir /etc/tuned/nothp_profile
```

2. Then create a new **tuned.conf** file for **nothp_profile**, and insert the new tuning info:

```
cat <<EOF > /etc/tuned/nothp_profile/tuned.conf
[main]
include= throughput-performance

[vm]
transparent_hugepages=never
```

```
EOF
```

3. Make the script executable

```
chmod +x /etc/tuned/nothp_profile/tuned.conf
```

4. Enable `nothp_profile` using the `tuned-adm` command.

```
tuned-adm profile nothp_profile
```

5. This change will immediately take effect and persist after reboots. To verify if THP are disabled or not, run below command:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
always madvise [never]
```

8.2. Putting `server.locks` directory into RAM

The `server.locks` directory is maintained in the `$P4ROOT` (so `/p4/1/root`) for a running server instance. This directory contains a tree of 0-length files (or 17 byte files in earlier p4d versions) used for lock coordination amongst p4d processes.

This directory can be removed every time the p4d instance is restarted, so it is safe to put it into a `tmpfs` filesystem (which by its nature does not survive a reboot).

Even on a large installation with many hundreds or thousands of users, this directory will be unlikely to exceed 64M. The files in this directory are 17 or 0 bytes depending on the p4d version; space is needed for inodes.

To do this, first determine if the setting will be global for all p4d servers at your site, or will be determined on a per-server machine basis. If set globally, the per-machine configuration described below **MUST** be done on all p4d server machines.

This should be done in a scheduled maintenance window.

For each p4d server machine (**all** server machines if you intend to make this a global setting), do the following as user `root`:

1. Create a local directory mount point, and change owner/group to `perforce:perforce` (or `$(OSUSER)` if SDP config specifies a different OS user, and whatever group is used):

```
mkdir /hxserverlocks
chown perforce:perforce /hxserverlocks
```

2. Add a line to `/etc/fstab` (adjusting appropriately if `$(OSUSER)` and group are set to something other

than `perforce:perforce`):

```
HxServerLocks /hxserverlocks tmpfs
uid=perforce,gid=perforce,size=64M,mode=0700 0 0
```

Note: The `64M` in the above example is suitable for many sites, including large ones. For servers with less available RAM, a smaller value is recommended, but no less than `128K`.

If multiple SDP instances are operated on the machine, the value must be large enough for all instances.

1. Mount the storage volume:

```
mount -a
```

2. Check it is looking correct and has correct ownership (`perforce` or `$(OSUSER)`):

```
df -h
ls -la /hxserverlocks
```

As user `perforce` (or `$(OSUSER)`), set the configurable `server.locks.dir`. This will be set in one of two ways, depending on whether it was set globally, or on a per-server machine.

First, set the shell environment for your instance:

```
source /p4/common/bin/p4_vars N
```

Replacing `N` with your instance name; `1` by default.

To set `server.locks.dir` globally, do:

```
p4 configure set server.locks.dir="/hxserverlocks${P4HOME}/server.locks"
```

e.g.

```
p4 configure set ${SERVERID}#server.locks.dir=/hxserverlocks${P4HOME}/server.locks
```

If you set this globally (without `serverid#` prefix), then you must ensure that all server machines running `p4d`, including replicas and edge servers, have a similarly named directory available (or bad things will happen!)

Consider failover options. A failover will, by nature, change the `ServerID` on a given machine. If `server.locks.dir` is set globally, and all machines have the

HxServerLocks configuration done as noted above, then the `server.locks.dir` setting is fully accounted for, and will not cause a problem in a failover situation.

If `server.locks.dir` is set on a per-machine basis, then you should ensure that every standby server has the same configuration with respect to `server.locks.dir` and the HxServerLocks filesystem as its target server. So any standby servers replicating from a commit server should have the same configuration as the commit server, and any standby servers replicating from an edge server should have the same configuration as the target edge server. For simplicity, using a global setting should be considered.

If you are defining server machine templates (such as an AMI in AWS or with Terraform or similar), the HxServerLocks configuration can and should be accounted for in the system template.

8.3. Installing monitoring packages

The `sysstat` and `sos` packages are recommended for helping investigate any performance issues on a server.

```
yum install sysstat sos
```

or

```
apt install sysstat sos
```

Then enable it:

```
systemctl enable --now sysstat
```

The reports are text based, but you can use kSar (<https://github.com/vlsi/ksar>) to visualize the data. If installed before `sosreport` is run, `sosreport` will include the `sysstat` data.

We also recommend `P4prometheus` - <https://github.com/perforce/p4prometheus>. See [Automated script installer for SDP instances](#) which makes it easy to install `node_exporter`, `p4prometheus` and monitoring scripts in the `crontab`

See an example of [interpreting prometheus metrics](#)

8.4. Optimizing the database files

The Perforce Server's database is composed of b-tree files. The server does not fully rebalance and compress them during normal operation. To optimize the files, you must checkpoint and restore the server. This normally only needs to be done very few months.

To minimize the size of back up files and maximize server performance, minimize the size of the `db.have` and `db.label` files.

8.5. P4V Performance Settings

These are covered in: <https://portal.perforce.com/s/article/2878>

8.6. Proactive Performance Maintenance

This section describes some things that can be done to proactively to enhance scalability and maintain performance.

8.6.1. Limiting large requests

To prevent large requests from overwhelming the server, you can limit the amount of data and time allowed per query by setting the `MaxResults`, `MaxScanRows` and `MaxLockTime` parameters to the lowest setting that does not interfere with normal daily activities. As a good starting point, set `MaxScanRows` to `MaxResults * 3`; set `MaxResults` to slightly larger than the maximum number of files the users need to be able to sync to do their work; and set `MaxLockTime` to 30000 milliseconds. These values must be adjusted up as the size of your server and the number of revisions of the files grow. To simplify administration, assign limits to groups rather than individual users.

To prevent users from inadvertently accessing large numbers of files, define their client view to be as narrow as possible, considering the requirements of their work. Similarly, limit users' access in the `protections` table to the smallest number of directories that are required for them to do their job.

Finally, keep triggers simple. Complex triggers increase load on the server.

8.6.2. Offloading remote syncs

For remote users who need to sync large numbers of files, Perforce offers a [proxy server](#). P4P, the Perforce Proxy, is run on a machine that is on the remote users' local network. The Perforce Proxy caches file revisions, serving them to the remote users and diverting that load from the main server.

P4P is included in the Windows installer. To launch P4P on Unix machines, copy the `/p4/common/etc/init.d/p4p_1_init` script to `/p4/1/bin/p4p_1_init`. Then review and customize the script to specify your server volume names and directories.

P4P does not require special hardware but it can be quite CPU intensive if it is working with binary files, which are CPU-intensive to attempt to compress. It doesn't need to be backed up. If the P4P instance isn't working, users can switch their port back to the main server and continue working until the instance of P4P is fixed.

Chapter 9. Tools and Scripts

This section describes the various scripts and files provided as part of the SDP package.

9.1. General SDP Usage

This section presents an overview of the SDP scripts and tools, with details covered in subsequent sections.

9.1.1. Linux

Most scripts and tools reside in `/p4/common/bin`. The `/p4/<instance>/bin` directory (e.g. `/p4/1/bin`) contains scripts or links that are specific to that instance such as wrappers for the `p4d` executable.

Older versions of the SDP required you to always run important administrative commands using the `p4master_run` script, and specify fully qualified paths. This script loads environment information from `/p4/common/bin/p4_vars`, the central environment file of the SDP, ensuring a controlled environment. The `p4_vars` file includes instance specific environment data from `/p4/common/config/p4_instance.vars` e.g. `/p4/common/config/p4_1.vars`. The `p4master_run` script is still used when running `p4` commands against the server unless you set up your environment first by sourcing `p4_vars` with the instance as a parameter (for bash shell: `source /p4/common/bin/p4_vars 1`). Administrative scripts, such as `daily_checkpoint.sh`, no longer need to be called with `p4master_run` however, they just need you to pass the instance number to them as a parameter.

When invoking a Perforce command directly on the server machine, use the `p4_instance` wrapper that is located in `/p4/instance/bin`. This wrapper invokes the correct version of the `p4` client for the instance. The use of these wrappers enables easy upgrades, because the wrapper is a link to the correct version of the `p4` client. There is a similar wrapper for the `p4d` executable, called `p4d_instance`.

This wrapper is important to handle case sensitivity in a consistent manner, e.g. when running a Unix server in case-insensitive mode. If you just execute `p4d` directly when it should be case-insensitive, then you may cause problems, or commands will fail.

Below are some usage examples for instance 1.

<i>Example</i>	<i>Remarks</i>
<code>/p4/common/bin/p4master_run 1 /p4/1/bin/p4_1 admin stop</code>	Run <code>p4 admin stop</code> on instance 1
<code>/p4/common/bin/live_checkpoint.sh 1</code>	Take a checkpoint of the live database on instance 1
<code>/p4/common/bin/p4login 1</code>	Log in as the perforce user (superuser) on instance 1.

Some maintenance scripts can be run from any client workspace, if the user has administrative access to Perforce.

9.1.2. Monitoring SDP activities

The important SDP maintenance and backup scripts generate email notifications when they complete.

For further monitoring, you can consider options such as:

- Making the SDP log files available via a password protected HTTP server.
- Directing the SDP notification emails to an automated system that interprets the logs.

9.2. Upgrade Scripts

9.2.1. get_helix_binaries.sh

Usage

USAGE for get_helix_binaries.sh v1.3.4:

```
get_helix_binaries.sh [-r <HelixMajorVersion>] [-b <Binary1>,<Binary2>,...] [-n] [-D]
```

or

```
get_helix_binaries.sh -h|-man
```

DESCRIPTION:

This script acquires Perforce Helix binaries from the Perforce FTP server.

The four Helix binaries that can be acquired are:

- * p4, the command line client
- * p4d, the Helix Core server
- * p4p, the Helix Proxy
- * p4broker, the Helix Broker

This script gets the latest patch of binaries for the current major Helix version. It is intended to acquire the latest patch for an existing install, or to get initial binaries for a fresh new install. It must be run from the /hxdepots/sdp/helix_binaries directory (or similar; the /hxdepots directory is the default but is subject to local configuration).

The helix_binaries directory is used for staging binaries for later upgrade with the SDP 'upgrade.sh' script (documented separately). This helix_binaries directory is used to stage binaries on the current machine, while the 'upgrade.sh' script updates a single SDP instance (of which there might be several on a machine).

The helix_binaries directory may not be in the PATH. As a safety feature, the 'verify_sdp.sh' will report an error if the 'p4d' binary is found outside /p4/common/bin in the PATH. The SDP 'upgrade.sh' check uses 'verify_sdp.sh' as part of its preflight checks, and will refuse to upgrade if any 'p4d' is

found outside /p4/common/bin.

When a newer major version of Helix binaries is needed, this script should not be modified directly. Instead, the recommended approach is to upgrade the SDP to get the latest version of SDP first, which will include a newer version of this script, as well as the latest 'upgrade.sh'. The 'upgrade.sh' script is updated with each major SDP version to be aware of any changes in the upgrade procedure for the corresponding p4d version. Upgrading SDP first ensures you have a version of the SDP that works with newer versions of p4d and other Helix binaries.

OPTIONS:

`-r <HelixMajorVersion>`

Specify the Helix Version, using the short form. The form is rYY.N, e.g. r21.2 to denote the 2021.2 release. The default: is r23.2

`-b <Binary1>[,<Binary2>,...]`

Specify a comma-delimited list of Helix binaries. The default is: p4 p4d p4broker p4p

`-n` Specify the '-n' (No Operation) option to show the commands needed to fetch the Helix binaries from the Perforce FTP server without attempting to execute them.

`-D` Set extreme debugging verbosity using bash 'set -x' mode.

HELP OPTIONS:

`-h` Display short help message

`-man` Display this manual page

EXAMPLES:

Note: All examples assume the SDP is in the standard location, /hxdepots/sdp.

Example 1 - Typical Usage with no arguments:

```
cd /hxdepots/sdp/helix_binaries
./get_helix_binaries.sh
```

This acquires the latest patch of all 4 binaries for the r23.2 release (aka 2023.2).

Example 2 - Specifying the major version:

```
cd /hxdepots/sdp/helix_binaries
./get_helix_binaries.sh -r r21.2
```

This gets the latest patch of for the 2021.2 release of all 4 binaries.

Note: Only supported Helix binaries are guaranteed to be available from the Perforce FTP server.

Note: Only the latest patch of any given binary is available from the Perforce FTP server.

Example 3 - Sample getting r22.2 and skipping the proxy binary (p4p):

```
cd /hxdepots/sdp/helix_binaries
./get_helix_binaries.sh -r r22.2 -b p4,p4d,p4broker
```

DEPENDENCIES:

This script requires outbound internet access. Depending on your environment, it may also require HTTPS_PROXY to be defined, or may not work at all.

If this script doesn't work due to lack of outbound internet access, it is still useful illustrating the locations on the Perforce FTP server where Helix Core binaries can be found. If outbound internet access is not available, use the '-n' flag to see where on the Perforce FTP server the files must be pulled from, and then find a way to get the files from the Perforce FTP server to the correct directory on your local machine, /hxdepots/sdp/helix_binaries by default.

EXIT CODES:

An exit code of 0 indicates no errors were encountered. A non-zero exit code indicates errors were encountered.

9.2.2. upgrade.sh

The `upgrade.sh` script is used to upgrade `p4d` and other Perforce Helix binaries on a given server machine.

The links for different versions of `p4d` are described in [Section A.1.3, “P4D versions and links”](#)

Usage

USAGE for upgrade.sh v4.12.2:

```
upgrade.sh <instance> [-p|-I] [-M] [-Od] [-Osp] [-c] [-y] [-L <log>] [-d|-D]
```

or

```
upgrade.sh [-h|-man]
```

DESCRIPTION:

This script upgrades the following Helix Core software:

- * p4d, the Perforce Helix Core server
- * p4broker, the Helix Broker server
- * p4p, the Helix Proxy server
- * p4, the command line client

The preferred process for using this script is to start with the services to be upgraded (p4d, p4broker, and/or p4p) up and running at the start of processing. The p4d service must be online if it is to be upgraded.

Details of each upgrade are described below. Prior to executing any upgrades, a preflight check is done to help ensure upgrades will go smoothly. Also, checks are done to determine what (if any) of the above software products need to be updated.

To prepare for an upgrade, new binaries must be update in the /p4/sdp/helix_binaries directory. This is generally done using the get_helix_binaries.sh script in that directory. Binaries in this directory are not referenced by live running servers, and so it is safe to upgrade files in this directory to stage for a future upgrade at any time. Also, the SDP standard PATH does not include this directory, as verified by the verify_sdp.sh script.

THE INSTANCE BIN DIR

The 'instance bin' directory, /p4/<instance>/bin, (e.g. /p4/1/bin for instance 1), is expected to contain *_init scripts for services that operate on the current machine.

For example, a typical commit server machine for instance 1 might have the following in /p4/1/bin:

- * p4broker_1_init script
- * p4broker_1 symlink
- * p4d_1_init script
- * p4d_1 symlink or script
- * p4_1 symlink (a reference to the 'p4' command line client)

A server machine for instance 1 that runs only the proxy server would have the following in /p4/1/bin:

- * p4p_1_init script
- * p4p_1 symlink
- * p4_1 symlink

The instance bin directory is never modified by the 'upgrade.sh' script. The addition of new binaries and update of symlinks occur in /p4/common/bin.

The existence of *_init scripts for any given binary determines whether this script attempts to manage the service on a given machine, stopping it before upgrades, restarting it afterward, and other processing in the case of p4d.

Note that Phase 2, adding new binaries and updating symlinks, will occur for all binaries for which new staged versions are available, regardless of whether they are operational on the given machine.

THE COMMON DIR

This script performs its operations in the SDP common bin dir, `/p4/common/bin`.

Unlike the instance bin directory, the `/p4/common/bin` directory is expected to be identical across all machines in a topology. Scripts and symlinks should always be the same, with only temporary differences while global topology upgrades are in progress.

Thus, all binaries available to be upgraded will be upgraded in Phase 2, even if the binary does not operate on the current machine. For example, if a new version of 'p4p' binary is available, a new version will be copied to `/p4/common/bin` and symlink references updated there. However, the p4p binary will not be stopped/started.

GENERAL UPGRADE PROCESS

This script determines what binaries need to be upgraded, based on what new binaries are available in the `/p4/sdp/helix_binaries` directory compared to what binaries the current instance uses.

There are 5 potential phases. Which phases execute depend on the set of binaries being upgraded. The phases are:

* PHASE 1 - Establish a clean rollback point.

This phase executes on the master if p4d is upgraded.

* PHASE 2 - Install new binaries and update SDP symlinks in `/p4/common/bin`.

This phase executes for all upgrades.

* PHASE 3 - Stop services to be upgraded.

This phase executes for all upgrades involving p4d, p4p, p4broker.

Only a 'p4' client only upgrade skips this phase.

* PHASE 4 - Perform p4d schema upgrades

This step involves the 'p4d -xu' processing. It executes if p4d is upgraded to a new major version, and occurs on the master as well as all replicas/edge servers. The behavior of 'p4d -xu' differs depending on whether the server is the master or a replica.

This phase is skipped if upgrading to a patch of the same major version, as patches do not require 'p4d -xu' processing.

* PHASE 5 - Start upgraded services.

This phase executes for all upgrades involving p4d, p4p, p4broker.

Only a 'p4' client only upgrade skips this phase.

SPECIAL CASE - TO OR THRU P4D 2019.1

If you are upgrading from a version that is older than 2019.1, services are NOT restarted after the upgrade in Phase 5, except on the master. Services must be restarted manually on all other servers.

For these 'to-or-thru' 2019.1 upgrades, after ensuring all replicas/edges are caught up (per 'p4 pull -lj'), shutdown all servers other than the master.

Proceeding outer-to-inner, execute this script like so on all machines except the master:

1. Deploy new executables in /p4/sdp/helix_binaries
2. Stop p4d.
3. Run 'verify_sdp.sh -skip cron,version'; fix problems if needed until it reports clean.
4. Run 'upgrade.sh -M' to update symlinks.
5. Do the upgrade manually with: p4d -xu
6. Leave the server offline.

On the master, execute like this:

1. Deploy new executables in /p4/sdp/helix_binaries
2. Run 'verify_sdp.sh -skip cron,version'; fix problems if needed until it reports clean.
3. upgrade.sh

When the script completes (it will wait for 'p4 storage' upgrades), restart services manually after the upgrade in the 'inner-to-outer' direction. Restart services on replicas/edges going inner-to-outer

This procedure requiring extra steps is specific to 'to-or-thru' P4D 2019.1 upgrades. For upgrades starting from P4D 2019.1 or later, things are simpler.

UPGRADES FOR P4D 2019.1+

For upgrades where the P4D start version is 2019.1 and going to any subsequent version, run this script going outer-to-inner. On each machine, it leaves the services online and running. Going in the outer-to-inner direction on all servers, do:

1. Deploy new executables in /p4/sdp/helix_binaries
2. Run 'verify_sdp.sh -skip cron,version'; fix problems if needed until it reports clean.
3. upgrade.sh

UPGRADE PREPARATION

The steps for deploying new binaries to server machines and running verify_sdp.sh (and potentially correcting any issues it discovers) can and should be done before the time or even day of any planned upgrade.

UPGRADING HELIX CORE - P4D

The p4d process, the Perforce Helix Core Server, is the center of the Perforce Helix universe, and the only server with a significant database component. Most of the upgrade phases above are about performing the p4d upgrade.

This 'upgrade.sh' script requires that the 'p4d' service be running at the beginning of processing if p4d is to be upgraded, and will abort if p4d is not running.

ORDER OF UPGRADES

Any given Perforce Helix installation will have least one p4d master server, and may have several other p4d servers deployed on different machines as replicas and edge servers. When upgrading multiple p4d servers for any given instance (i.e. any given data set, with a unique set of changelist numbers and users), the order in which upgrades are performed matters. Upgrades must be done in "outer to inner" order.

The master server, at the center of the topology, is the innermost server and must be upgraded last. Any replicas or edge servers connected directly to the master constitute the next outer circle. These can be upgraded in any order relative to each other, but must be done before the master and after any replicas farther out from the master in the topology. So this 'upgrade.sh' script should be run first on the server machines that are "outermost" from the master from a replication perspective, and moving inward. The last run is done on the master server machine.

Server machines running only proxies and brokers do not have a strict order dependency for upgrades. These are commonly done in the same "outer to inner" methodology as p4d for process consistency rather than strict technical need.

See the [SDP_Guide.Unix.html](#) for more information related to performing global topology upgrades.

COMMIT SERVER JOURNAL ROTATIONS

This script helps minimize downtime for upgrades by taking advantage of the SDP offline checkpoint mechanism. Rather than wait for a full checkpoint, a journal is rotated and replayed to the offline_db. This typically takes very little time compared to a checkpoint, reducing downtime needed for the overall upgrade. It also prepares the offline_db in case a rollback is needed.

When the commit server is upgraded, two rotations of the commit server's journal occur during processing for major upgrades, and a single journal rotation is done for patch upgrades. The first journal rotation occurs before any upgrade processing occurs, i.e. before the new binaries are added and symlinks are updated. This gives a clean rollback point. This journal is immediately replayed to the offline_db.

Later, after p4d has started performs its journaled upgrade processing, a second

journal rotation occurs in Phase 5 if a major upgrade was done. This second journal rotation captures all upgrade-related processing in a separately numbered journal. This second journal is not applied to the `offline_db` by this script. Instead, the replay of the second journal to the `offline_db` will occur the next time a call is made to the `daily_checkpoint.sh` or `rotate_journal.sh`, e.g. via routine `crontab`. For a p4d patch upgrade, there will not be any upgrade processing.

In the very unlikely event that a rollback were to ever be needed, the `offline_db` is left in a state that it could be used for a fast rollback on the commit server.

MULTI-SERVER OUTER-TO-INNER UPGRADES

Before starting an outer-to-inner upgrade involving multiple p4d servers, (standby, edge, and other p4d replica servers), a manual journal rotation should be done on the commit server before starting to call `upgrade.sh` on each of the p4d servers in outer-to-inner order. Take note of the journal counter used for this pre-start journal rotation. It can be useful in event of a rollback. That journal may need to be replayed to the `offline_db` on all servers other than the commit in a rollback scenario.

In preparation in days or weeks before an upgrade, every p4d server in the topology should be checked to ensure its `offline_db` is healthy and current.

ROLLBACK

In the very unlikely event that a rollback is needed, bear in mind the following:

- * There is no standard procedure for rolling back, because a procedure would need to take into account the reason a decision was made to rollback. Presumably the decision would be driven by some kind of failure. A large factor in determining whether rollback is practical is the point in the process at which a rollback is needed. In some situations, a 'Fix and Roll Forward' approach may be more pragmatic than a rollback, and should always be considered.

- * This script and supporting documentation will help prepare your data for as smooth a rollback as possible should it ever become necessary.

- * To best prepare for a rollback, it is essential to manage user lockout as part of your overall maintenance procedure. Then let users back in after you have confirmed you are moving forward. User lockout is outside the scope of this script, but can be managed using several possible methods such as:

- Crafting a special Protections table to be used during maintenance,
- Using "Down for Maintenance" brokers,
- Using network and/or on-host firewall rules,
- Using temporary ports for maintenance.

- * If Phase 2 (update of symlinks and binaries) completed and must be undone, than can be achieved by putting the pre-upgrade binaries in place in the directory `/p4/sdp/helix_binaries`, named simply `p4`, `p4d`, `p4broker`, and `p4p`. Then run a command like this example for Instance 1:

```
upgrade.sh 1 -M -I -y
```

This will change symlinks back to reference the older versions. The new binaries will still exist in /p4/common/bin, but will no longer be referenced for Instance 1.

UPGRADING HELIX BROKER

Helix Broker (p4broker) servers are commonly deployed on the same machine as a Helix Core server, and can also be deployed on stand-alone machines (e.g. deployed to a DMZ host to provide secure access outside a corporate firewall).

Helix Brokers configured in the SDP environment can use a default configuration file, and may have other configurations. The default configuration is the one defined in /p4/common/config/p4_N.broker.cfg (or a host-specific override file if it exists named /p4/common/config/p4_N.broker.<short_hostname>.cfg). Other broker configurations may exist, such as a DFM (Down for Maintenance) broker config /p4/common/config/p4_N.broker.dfm.cfg.

During upgrade processing, this 'upgrade.sh' script only stops and restarts the broker with the default configuration. Thus, if coordinating DFM brokers, first manually shutdown the default broker and start the DFM brokers before calling this script. This script will leave the DFM brokers running while adding the new binaries and updating the symlinks. (Note: Depending on how services are configured, this DFM configuration might not survive a machine reboot. typically the default broker will come online after a machine reboot).

This 'upgrade.sh' script will stop the p4broker service if it is running at the beginning of processing. If it was stopped, it will be restarted after the new binaries are in place and symlinks are updated. If p4broker was not running at the start of processing, new binaries are added and symlinks updated, but the p4broker server will not be started.

UPGRADING HELIX PROXY

Helix Proxy (p4p) are commonly deployed on a machine by themselves, with no p4d and no broker. It may also be run on the same machine as p4d.

This 'upgrade.sh' script will stop the p4p service if it is running at the beginning of processing. If it was stopped, it will be restarted after the new binaries are in place and symlinks are updated. If p4p was not running at the start of processing, new binaries are added and symlinks updated, but the p4p server will not be started.

UPGRADING HELIX P4 COMMAND LINE CLIENT

The command line client, 'p4', is upgraded in Phase 2 by addition of new binaries and updating of symlinks.

STAGING HELIX BINARIES

If your server can reach the Perforce FTP server over the public internet, a script can be used from the /p4/sdp/helix_binaries directory to get the latest binaries:

```
$ cd /p4/sdp/helix_binaries
$ ./get_helix_binaries.sh
```

If your server cannot reach the Perforce FTP server, perhaps due to outbound network firewall restrictions or operating on an "air gapped" network, use the '-n' option to see where Helix binaries can be acquired from:

```
$ cd /p4/sdp/helix_binaries
$ ./get_helix_binaries.sh -n
```

OPTIONS:

<instance>

Specify the SDP instance name to add. This is a reference to the Perforce Helix Core data set. This defaults to the current instance based on the \$SDP_INSTANCE shell environment variable. If the SDP shell environment is not loaded, this option is required.

-p Specify '-p' to halt processing after preflight checks are complete, and before actual processing starts. By default, processing starts immediately upon successful completion of preflight checks.

-Od

Specify '-Od' to override the rule preventing downgrades.

WARNING: This is an advanced option intended for use by or with the guidance of Perforce Support or Perforce Consulting.

-Osp

Specify '-Osp' to override the sudo preflight, skipping that check.

WARNING: This is an advanced option intended for use by or with the guidance of Perforce Support or Perforce Consulting.

-I

Specify '-I' to ignore preflight errors. Use of this flag is **STRONGLY DISCOURAGED**, as the preflight checks are essential to ensure a safe and smooth migration. If used, preflight checks are still done so their errors are recorded in the upgrade log, and then the migration will attempt to proceed.

WARNING: This is an advanced option intended for use by or with the guidance of Perforce Support or Perforce Consulting.

-M

Specify '-M' if you plan to do a manual upgrade. With this option, only Phase 2 processing, adding new staged binaries and updating

symlinks, is done by this script.

If '-M' is used, this script does not check that services to be upgraded are online at the start of processing, nor does it attempt to start to stop services. If '-M' is used, the services should be stopped manually before calling this script, and then started manually after.

WARNING: This is an advanced option intended for use by or with the guidance of Perforce Support or Perforce Consulting.

-c

Specify '-c' to execute a command to upgrade the Protections table comment format after the p4d upgrade, by using a command like:

```
p4 protect --convert-p4admin-comments -o | p4 -s protect -i
```

By default, this Protections table conversion is not performed. In some environments with custom policies related to update of the protections table, this command may not work.

The new style of comments and the '--convert-p4admin-comments' option was introduced in P4D 2016.1.

-L <log>

Specify the path to a log file, or the special value 'off' to disable logging. By default, all output (stdout and stderr) goes to this file in the /p4/N/logs directory (where N is the SDP instance name):

```
upgrade.p4_N.<datestamp>.log
```

NOTE: This script is self-logging. That is, output displayed on the screen is simultaneously captured in the log file. Redirection operators like '> log' and '2>&1' are not required, nor is 'tee'.

Logging can only be disabled with '-L off' if the '-n' or '-p' flags are used. Disabling logging for actual upgrades is not allowed.

-y

Specify the '-y' option to confirm that the upgrade should be done.

By default, this script operates in No-Op mode, meaning no actions that affect data or structures are taken. Instead, commands that would be run are displayed. This mode can be educational, showing various steps that will occur during an actual upgrade.

DEBUGGING OPTIONS:

-d Increase verbosity for debugging.

-D Set extreme debugging verbosity, using bash '-x' mode. Also implies -d.

HELP OPTIONS:

```
-h Display short help message
-man Display man-style help message
```

EXAMPLES:**EXAMPLE 1: Preflight Only**

To see if an upgrade is needed for this instance, based on binaries staged in /p4/sdp/helix_binaries, use the '-p' flag to execute only the preflight checks, and disable logging, as in this example:

```
$ cd /p4/common/bin
$ ./upgrade.sh 1 -p -L off
```

EXAMPLE 2: Typical Usage

Typical usage is with just the SDP instance name as an argument, e.g. instance '1', and no other parameters, as in this example:

```
$ cd /p4/common/bin
$ ./upgrade.sh 1
```

This first runs preflight checks, and aborts if preflight checks detected any issues. The it gives a preview of the upgrade. A successful preview completes with a line near the end that looks like this sample:

```
Success: Finished p4_1 Upgrade.
```

If the preview is successful, then proceed with the real upgrade using the -y flag:

```
$ ./upgrade.sh 1 -y
```

EXAMPLE 3: Simplified

If the standard SDP shell environment is loaded, upgrade.sh will be in the path, so the 'cd' command to /p4/common/bin is not needed. Also, the SDP_INSTANCE shell environment variable will be defined, so the 'instance' parameter can be dropped, with simply a call to the script needed. First do a preview:

```
$ upgrade.sh
```

Review the output of the preview, looking for the 'Success: Finished' message near the end of the output. If that exists, then execute again with the '-y' flag to execute the actual migration:

```
$ upgrade.sh -y
```

CUSTOM PRE- AND POST- UPGRADE AUTOMATION HOOKS:

This script can execute custom pre- and post- upgrade scripts. This can be useful to incorporate site-specific elements of an upgrade.

If the file `/p4/common/site/upgrade/pre-upgrade.sh` exists and is executable, it will be executed as a pre-upgrade script. If the file `/p4/common/site/upgrade/post-upgrade.sh` exists and is executable, it will be executed as a post-upgrade script.

Pre- and post- upgrade scripts are called with an SDP instance parameter, and an optional `-y` flag to confirm actual processing is to be done. Custom scripts are expected to operate in preview mode by default, taking no actions that affect data (just as this script behaves). If this `upgrade.sh` script is given the `-y` flag, that option is passed to the custom script as well, indicating active processing should occur.

Pre- and post- upgrade scripts are expected to exit with a zero exit code to indicate success, and non-zero to indicate failure.

The custom pre-upgrade script is executed after standard preflight checks complete successfully. If the `-I` flag is used to ignore the status of preflight checks, the custom pre-upgrade script is executed regardless of the status of preflight checks. Preflight checks are executed before actual upgrade processing commences. If a custom pre-upgrade script indicates a failure, the overall upgrade process aborts.

The post-upgrade custom script is executed after the main upgrade is successful.

Success or failure of pre- and post- upgrade scripts is reported in the log. These scripts do not require independent logging, as all standard and error output is captured in the log of this `upgrade.sh` script.

TIP: Be sure to fully test custom scripts in a test environment before incorporating them into an upgrade on production systems.

SEE ALSO:

The `/p4/common/bin/verify_sdp.sh` script is used for preflight checks.

The `/p4/sdp/helix_binaries/get_helix_binaries.sh` script acquires new binaries for upgrades.

Both scripts sport the same `-h` (short help) and `-man` (full manual) usage options as this script.

LIMITATIONS:

This script does not handle upgrades of `'p4dtg'`, Helix Swarm, Helix4Git, or any other software. It only handles upgrades of `p4d`, `p4p`, `p4broker`, and the `p4` client binary on the SDP-managed

server machine on which it is executed.

9.2.3. sdp_upgrade.sh

This script will perform an upgrade of the SDP itself - see [Section 7.3, “Upgrading the SDP”](#)

Usage

USAGE for sdp_upgrade.sh v1.7.8:

```
sdp_upgrade.sh [-y] [-p] [-L <log>|off] [-D]
```

or

```
sdp_upgrade.sh -h|-man
```

This script must be executed from the 'sdp_upgrade' directory in the extracted SDP tarball.

Typical operation starts like this:

```
cd /hxdepots/downloads/new/sdp/Server/Unix/p4/common/sdp_upgrade
./sdp_upgrade.sh -h
```

DESCRIPTION:

This script upgrades Perforce Helix Server Deployment Package (SDP) from SDP 2020.1 to the version included in the latest SDP version, SDP 2022.2.

== Pre-Upgrade Planning ==

This script will upgrade the SDP if the pre-upgrade starting SDP version is SDP 2020.1 or later, including any/all patches of SDP 2020.1.

If the current SDP version is older than 2020.1, it must first be upgraded to SDP 2020.1 using the SDP Legacy Upgrade Guide. For upgrading from pre-20.1 versions dating back to 2007, in-place or migration-style upgrades can be done. See:

https://swarm.workshop.perforce.com/projects/perforce-software-sdp/view/main/doc/SDP_Legacy_Upgrades.Unix.html

The SDP should always be upgraded to the latest version first before Helix Core binaries p4d/p4broker/p4p are upgraded using the SDP upgrade.sh script.

Upgrading the SDP first ensures the version of the SDP you have

is compatible with the latest versions of p4d/p4broker/p4p/p4, and will always be compatible with all supported versions of these Helix Core binaries.

When this script is used, i.e. when the current SDP version is 2020.1 or newer, the SDP upgrade procedure does not require downtime for any running Perforce Helix services, such as p4d, p4broker, or p4p. This script is safe to run in environments where live p4d instances are running, and does not require p4d, p4broker, p4p, or any other services to be stopped or upgraded. Upgrade of the SDP is cleanly separate from the upgrade the Helix Core binaries. The upgrade of the SDP can be done immediately prior to Helix Core upgrades, or many days prior.

There can be multiple SDP instances on a given server machine. This script will upgrade the SDP on the machine, and thus after the upgrade all instances will immediately use new SDP scripts and updated instance configuration files, e.g. the /p4/common/config/p4_N.vars files. However, all instances will continue running the same Helix Core binaries. Any live running Helix Core server process on the machine are unaffected by the upgrade of SDP.

This script will upgrade the SDP on a single machine. If your Perforce Helix topology has multiple machines, the SDP should be upgraded on all machines. The upgrade of SDP on multiple machines can be done in any order, as there is no cross-machine dependency requiring the SDP to be the same version. (The order of upgrade of Helix Core services and binaries such as p4d in global topologies with replicas and edge servers does matter, but is outside the scope of this script).

Planning Recap:

1. The SDP can be upgraded without downtime when this script is used, i.e. when the starting SDP version is 2020.1 or later.
2. Upgrade SDP on all machines, in any order, before upgrading p4d and other Helix binaries.

== NFS Sharing of HxDepots ==

In some environments, the HxDepots volume is shared across multiple server machines with NFS, typically mounted as /hxdepots. This script updates the /hxdepots/p4/common and /hxdepots/sdp directories, both of which are on the NFS mount. Thus upgrading SDP on a single machine will effectively and immediately upgrade the SDP on all machines that share /hxdepots from the same NFS-mounted storage. This is a safe and valid configuration, as upgrading the SDP does not affect any live running p4d servers.

== Acquiring the SDP Package ==

This script is part of the SDP package (tarball). It must be run from an extracted tarball directory. Acquiring the SDP tarball is a manual operation.

The SDP tarball must be extracted such that the 'sdp' directory appears as

<HxDepots>/downloads/new/sdp, where <HxDepots> defaults to /hxdepots. To determine the value for <HxDepots> at your site you can run the following:

```
bash -c 'cd /p4/common; d=$(pwd -P); echo ${d%/p4/common}'
```

On this machine, that value is: /hxdepots

Following are sample commands to acquire the latest SDP, to be executed as the user performce:

```
cd /hxdepots
[[ -d downloads ]] || mkdir downloads
cd downloads
[[ -d new ]] && mv new old.$(date +%Y%m%d-%H%M')
curl -s -k -O https://swarm.workshop.perforce.com/projects/perforce-software-
sdp/download/downloads/sdp.Unix.tgz
mkdir new
cd new
tar -xzf ../sdp.Unix.tgz
```

After extracting the SDP tarball, cd to the directory where this sdp_upgrade.sh script resides, and execute it from there.

```
cd /hxdepots/downloads/new/sdp/Server/Unix/p4/common/sdp_upgrade
./sdp_upgrade.sh -man
```

== Preflight Checks ==

Prior to upgrading, preflight checks are performed to ensure the upgrade can be completed successfully. If the preflight checks fail, the upgrade will not start.

Sample Preflight Checks:

- * The existing SDP version is verified to be SDP 2020.1+.
- * Various basic SDP structural checks are done.
- * The /p4/common/bin/p4_vars is checked to confirm it can be upgraded.
- * All /p4/common/config/p4_N.vars files are checked to confirm they can be upgraded.

== Automated Upgrade Processing ==

Step 1: Backup /p4/common.

The existing <HxDepots>/p4/common structure is backed up to:

```
<HxDepots>/p4/common.bak.<YYYYMMDD-hhmm>
```

Step 2: Update /p4/common.

The existing SDP /p4/common structure is updated with new

versions of SDP files.

Step 3: Generate the SDP Environment File.

Regenerate the SDP general environment file,
/p4/common/bin/p4_vars.

The template is /p4/common/config/p4_vars.template.

Step 4: Generate the SDP Instance Files.

Regenerate the SDP instance environment files for all instances based on the new template.

The template is /p4/common/config/instance_vars.template.

For Steps 3 and 4, the re-generation logic will preserve current settings. If upgrading from SDP r20.1, any custom logic that exists below the '### MAKE LOCAL CHANGES HERE' tag will be split into separate files. Custom logic in p4_vars will be moved to /p4/common/site/config/p4_vars.local. Custom logic in p4_N.vars files will be moved to /p4/common/site/config/p4_N.vars.local.

Note: Despite these changes, the mechanism for loading the SDP shell environment remains unchanged since 2007, so it looks like:

```
$ source /p4/common/bin/p4_vars N
```

Changes to the right-side of assignments for specific are preserved for all defined SDP settings. For p4_vars, preserved settings are:

- OSUSER (determined by current owner of /p4/common)
- KEEPLLOGS
- KEEPCKPS
- KEEPJNLS

For instance_vars files, preserved settings are:

- MAILTO
- MAILFROM
- P4USER
- P4MASTER_ID
- SSL_PREFIX
- P4PORTNUM
- P4BROKERPORTNUM
- P4MASTERHOST
- PROXY_TARGET
- PROXY_PORT
- PROXY_MON_LEVEL
- PROXY_V_FLAGS
- P4DTG_CFG
- SNAPSHOT_SCRIPT
- SDP_ALWAYS_LOGIN

- SDP_AUTOMATION_USERS
- SDP_MAX_START_DELAY_P4D
- SDP_MAX_START_DELAY_P4BROKER
- SDP_MAX_START_DELAY_P4P
- SDP_MAX_STOP_DELAY_P4D
- SDP_MAX_STOP_DELAY_P4BROKER
- SDP_MAX_STOP_DELAY_P4P
- VERIFY_SDP_SKIP_TEST_LIST
- The 'umask' setting.
- KEEPPLOGS (if set)
- KEEPCKPS (if set)
- KEEPJNLS (if set)

Note that the above list excludes any values that are calculated.

Step 5: Remove Deprecated Files.

Deprecated files will be purged from the SDP structure. The list of files to be cleaned are listed in this file:

```
/hxdepots/downloads/new/sdp/Server/Unix/p4/common/sdp_upgrade/deprecated_files.txt
```

Paths listed in this file are relative to the '/p4' directory (or more accurately the SDP Install Root directory, which is always '/p4' except in SDP test production environments).

Step 6: Update SDP crontabs.

No crontab updates are required for this SDP upgrade.

== Post-Upgrade Processing ==

This script provides guidance on any post-processing steps. For some releases, this may include upgrades to crontabs.

OPTIONS:

-y Specify the '-y' option to confirm that the SDP upgrade should be done.

By default, this script operates in No-Op mode, meaning no actions that affect data or structures are taken. Instead, commands that would be run are displayed. This mode can be educational, showing various steps that will occur during an actual upgrade.

-p Specify '-p' to halt processing after preflight checks are complete, and before actual processing starts. By default, processing starts immediately upon successful completion of preflight checks.

-L <log>

Specify the log file to use. The default is /tmp/sdp_upgrade.<timestamp>.log

The special value 'off' disables logging to a file. This cannot be

specified if '-y' is used.

-d Enable debugging verbosity.

-D Set extreme debugging verbosity.

HELP OPTIONS:

-h Display short help message

-man Display man-style help message

FILES AND DIRECTORIES:

Name: SDPCommon

Path: /p4/common

Notes: This sdp_upgrade.sh script updates files in and under this folder.

Name: HxDepots

Default Path: /hxdepots

Notes: The folder containing versioned files, checkpoints, and numbered journals, and the SDP itself. This is commonly a mount point.

Name: DownloadsDir

Default Path: /hxdepots/downloads

Name: SDPInstallRoot

Path: /p4

EXAMPLES:

This script must be executed from 'sdp_upgrade' directory in the extracted SDP tarball. Typical operation starts like this:

```
cd /hxdepots/downloads/new/sdp/Server/Unix/p4/common/sdp_upgrade
./sdp_upgrade.sh -h
```

All following examples assume operation from that directory.

Example 1: Prelight check only:

```
sdp_upgrade.sh -p
```

Example 2: Preview mode:

```
sdp_upgrade.sh
```

Example 3: Live operation:

```
sdp_upgrade.sh -y
```

LOGGING:

This script generates a log file, ~/sdp_upgrade.<timestamp>.log by default. See the '-L' option above.

CUSTOM PRE- AND POST- UPGRADE AUTOMATION HOOKS:

This script can execute custom pre- and post- upgrade scripts. This can be useful to incorporate site-specific elements of an SDP upgrade.

If the file `/p4/common/site/upgrade/pre-sdp_upgrade.sh` exists and is executable, it will be executed as a pre-upgrade script. If the file `/p4/common/site/upgrade/post-sdp_upgrade.sh` exists and is executable, it will be executed as a post-upgrade script.

Pre- and post- upgrade scripts are passed the `'-y'` flag to confirm actual processing is to be done. Custom scripts are expected to operate in preview mode by default, taking no actions that affect data (just as this script behaves). If this `sdp_upgrade.sh` script is given the `'-y'` flag, that option is passed to the custom script as well, indicating active processing should occur.

Pre- and post- upgrade scripts are expected to exit with a zero exit code to indicate success, and non-zero to indicate failure. The custom pre-upgrade script is executed after standard preflight checks complete successfully. Preflight checks are executed before actual upgrade processing commences. If a custom pre-upgrade script indicates a failure, the overall upgrade process aborts.

The post-upgrade custom script is executed after the main SDP upgrade is successful.

Success or failure of pre- and post- upgrade scripts is reported in the log. These scripts do not require independent logging, as all standard and error output is captured in the log of this `sdp_upgrade.sh` script.

TIP: Be sure to fully test custom scripts in a test environment before incorporating them into an upgrade on production systems.

EXIT CODES:

An exit code of `0` indicates no errors were encountered during the upgrade. A non-zero exit code indicates the upgrade was aborted or failed.

9.3. Legacy Upgrade Scripts

9.3.1. `clear_depot_Map_fields.sh`

The `clear_depot_Map_fields.sh` script is used when upgrading to SDP from versions earlier than SDP 2020.1. Its usage is discussed in [SDP Legacy Upgrade Guide \(for Unix\)](#).

Usage

USAGE for `clear_depot_Map_fields.sh v1.2.0`:

```
clear_depot_Map_fields.sh [-i <instance>] [-L <log>] [-v<n>] [-p|-n] [-D]
```

or

```
clear_depot_Map_fields.sh [-h|-man|-V]
```

DESCRIPTION:

This script obsoletes the SetDefaultDepotSpecMapField.py trigger.

It does so by following a series of steps. First, it ensures that the configurable server.depot.root is set correctly, setting it if it is not already set.

Next, the Triggers table is checked to ensure the call to the SetDefaultDepotSpecMapField.py is not called; it is deleted from the Triggers table if found.

Last, it resets the 'Map:' field of depot specs for depot types where that is appropriate, setting it to the default value of '<DepotName>/...', so that it honors the server.depot.root configurable. This is done for depots of these types:

- * stream
- * local
- * spec
- * unload
- * graph

but not these:

- * archive
- * remote

If an unknown depot type is encountered, the 'Map:' field is reset as well if it is set.

This script does a preflight check first, reporting any cases where the starting conditions are not as expected. These conditions are treated as Errors, and will abort processing:

- * Depot Map field set to something other than the default.
- * Configurable server.depot.root is set, but to something other than what it should be.

The following are treated as Warnings, and will be reported but will not prevent processing.

- * Configurable server.depot.root is already set.
- * SetDefaultDepotSpecMapField.py not found in triggers.
- * Depot already has 'Map:' field set to the default value: <DepotName>/...

OPTIONS:

`-v<n>` Set verbosity 1-5 (`-v1` = quiet, `-v5` = highest).

`-L <log>`

Specify the path to a log file, or the special value 'off' to disable logging. By default, all output (stdout and stderr) goes to `EDITME_DEFAULT_LOG`

NOTE: This script is self-logging. That is, output displayed on the screen is simultaneously captured in the log file. Do not run this script with redirection operators like `> log` or `>&1`, and do not use 'tee.'

`-p` Run preflight checks only, and then stop. By default, actual changes occur if preflight checks find no issues.

`-n` No-Op. No actions are taken that would affect data significantly; instead commands are displayed rather than executed.

`-D` Set extreme debugging verbosity.

HELP OPTIONS:

`-h` Display short help message

`-man` Display man-style help message

`-V` Display version info for this script and its libraries.

EXAMPLES:

A typical flow for this script is to do a preflight first, and then a live run, for any given instance:

```
clear_depot_Map_fields.sh -i 1 -p
```

```
clear_depot_Map_fields.sh -i 1
```

Note that if using `'-n'`, the `'-v5'` flag should also be used.

9.4. Core Scripts

The core SDP scripts are those related to checkpoints and other scheduled operations, and all run from `/p4/common/bin`.

If you `source /p4/common/bin/p4_vars <instance>` then the `/p4/common/bin` directory will be added to your `$PATH`.

9.4.1. p4_vars

The `/p4/common/bin/p4_vars` defines the SDP shell environment, as required by the Perforce Helix server process. This script uses a specified instance number as a basis for setting environment variables. It will look for and open the respective `p4_<instance>.vars` file (see next section).

This script also sets server logging options and configurables.

It is intended to be used by other scripts for common environment settings, and also by users for setting the environment of their Bash shell.

Usage

```
source /p4/common/bin/p4_vars 1
```

See also: [Section 5.3, “Setting your login environment for convenience”](#)

9.4.2. p4_<instance>.vars

Defines the environment variables for a specific instance, including P4PORT etc.

This script is called by [Section 9.4.1, “p4_vars”](#) - it is not intended to be called directly by a user.

For instance **1**:

```
p4_1.vars
```

For instance **art**:

```
p4_art.vars
```

Occasionally you may need to edit this script to update variables such as **P4MASTERHOST** or similar.

Location: /p4/common/config

9.4.3. p4master_run

The `/p4/common/bin/p4master_run` is a wrapper script to other SDP scripts. This ensures that the shell environment is loaded from `p4_vars` before executing the script. It provides a `-c` flag for silent operation, used in many crontab so that email is sent from the scripts themselves.

This is especially useful for calling scripts that do not set their own shell environment, such as Python or Perl scripts. Historically it was used as a wrapper for all SDP scripts.

Many of the bash shell scripts in the SDP set their own environment (by doing `source /p4/common/bin/p4_vars N` for their instance); those bash shell scripts do **not** need to be called with the `p4master_run` wrapper.

9.4.4. daily_checkpoint.sh

The `/p4/common/bin/daily_checkpoint.sh` script configured by default to run six days a week using crontab. The script:

- truncates the journal
- replays it into the `offline_db` directory

- creates a new checkpoint from the resulting database files
- recreates the `offline_db` database from the new checkpoint.

This procedure rebalances and compresses the database files in the `offline_db` directory.

These can be rotated into the live (`root`) database, by the script [Section 9.4.12](#), “`refresh_P4ROOT_from_offline_db.sh`”

Usage

```
/p4/common/bin/daily_checkpoint.sh <instance>
/p4/common/bin/daily_checkpoint.sh 1
```

9.4.5. keep_offline_db_current.sh

The `/p4/common/bin/keep_offline_db_current.sh` script is for use only on a standby replica. It will not run on any other type of replica.

This script ensures the `offline_db` has the most current journals replayed.

It is intended for use on standby replicas as an alternative to `sync_replica.sh` or `replica_cleanup.sh`. It is ideal for use in an environment where the checkpoints folder of the P4TARGET server is shared (e.g. via NFS) with this server.

This script does NOT do full checkpoint operations, and requires that the `offline_db` be in a good state before starting — this is verified with a call to `verify_sdp.sh`.

This uses `checkpoint.log` as its primary log. It is only intended for use on a machine where other scripts that update `checkpoint.log` don't run, e.g. `daily_checkpoint.sh`, `live_checkpoint.sh`, or `rotate_journal.sh`.

Usage

```
/p4/common/bin/keep_offline_db_current.sh <instance>
/p4/common/bin/keep_offline_db_current.sh 1
```

9.4.6. live_checkpoint.sh

The `/p4/common/bin/live_checkpoint.sh` is used to initialize the SDP `offline_db`. It must be run once, typically manually during initial installation, before any other scripts that rely on the `offline_db` can be used, such as `daily_checkpoint.sh` and `rotate_journal.sh`.

This script can also be used in some cases to repair the `offline_db` if it has become corrupt, e.g. due to a sudden power loss while checkpoint processing was running.

Be aware this script locks the live database for the duration of the checkpoint which can take hours for a large installation (please check the `/p4/1/logs/checkpoint.log` for the most recent output of `daily_checkpoint.sh` to see

how long checkpoints take to create/restore).

Note that when a `live_checkpoint.sh` runs, the server will be unresponsive to users for a time. On a new installation this "hang time" will be imperceptible, but over time it can grow to minutes and eventually hours. The idea is that `live_checkpoint.sh` should be used only very sparingly, and is not scheduled as a routine operation.

This performs the following actions:

- Does a journal rotation, so the active P4JOURNAL file becomes numbered.
- Creates a checkpoint from the live database db.* files in the P4ROOT.
- Recovers the `offline_db` database from that checkpoint to rebalance and compress the files

Run this script when creating the server instance and if an error occurs while replaying a journal during the off-line checkpoint process.

Usage

```
/p4/common/bin/live_checkpoint.sh <instance>
/p4/common/bin/live_checkpoint.sh 1
```

9.4.7. mkrep.sh

The SDP `mkrep.sh` script should be used to expand your Helix Topology, e.g. adding replicas and edge servers.

Usage

USAGE for mkrep.sh v3.2.1:

```
mkrep.sh -t <Type> -s <Site_Tag> -r <Replica_Host> [-f <From_ServerID>] [-os] [-p] [-N
<N>] [-i <SDP_Instance>] [-L <log>] [-v<n>] [-n] [-D]
```

or

```
mkrep.sh [-h|-man|-V]
```

DESCRIPTION:

This script simplifies the task of creating Helix Core replicas and edge servers, and helps ensure they are setup with best practices.

This script executes as two phases. In Phase 1, this script does all the metadata configuration to be executed on the master server that must be baked into a seed checkpoint for creating the replica/edge. This essentially captures the planning for a new replica, and can be done before the physical infrastructure (e.g. hardware, storage, and networking) is ready. Phase 1, fully automated by this script, takes only seconds to run.

In Phase 2, this script provides information for the manual steps needed to create, transfer, and load seed checkpoints onto the replica/edge. The guidance is specific to type of replica created, based on the command line flags provided to this script. This processing can take a while for large data sets, as it involves creating and transporting checkpoints.

Before using this script, a set of geographic site tags must be defined. See the FILES: below for details on a site tags.

This script adheres to the these SDP Standards:

* Server Spec Naming Standard:

https://swarm.workshop.perforce.com/projects/perforce-software-sdp/view/main/doc/SDP_Guide.Unix.html#_server_spec_naming_standard

* Journal Prefix Standard: https://swarm.workshop.perforce.com/projects/perforce-software-sdp/view/main/doc/SDP_Guide.Unix.html#_the_journalprefix_standard

In Phase 1, this script does the following to help create a replica or edge server:

- * Generates the server spec for the the replica.
- * Generates a server spec for master server (if needed).
- * Sets configurables ('p4 configure' settings) for replication.
- * Selects the correct 'Services' based on replica type.
- * Creates service user for the replica, and sets a password.
- * Creates service user for the master (if needed), and sets a password.
- * Adds newly created service users to the group 'ServiceUsers'.
- * Verifies the group ServiceUsers is granted super access in the protections table (and with the '-p', updates Protections).

After these steps are completed, in Phase 2, detailed instructions are presented to guide the user through the remaining steps needed to complete the deployment of the replica. This starts with creating a new checkpoint to capture all the metadata changes made by this script in Phase 1.

SERVICE USERS:

Service users created by this type are always of type 'service', and so will not consume a licensed seat.

Service users also have an 'AuthMethod' of 'perforce' (not 'ldap') as is required by 'p4d' for 'service' users. Passwords set for service users are long 32 character random strings that are not stored, as they are never needed. Login tickets for service users are generated using: `p4login -service -v`

OPTIONS:

`-t <Type>[N]`

Specify the replica type tag. The type corresponds to the 'Type:' and 'Services:' field of the server spec, which describes the type of services offered by a given replica.

Valid type values are:

- * ha: High Availability standby replica, for 'p4 failover' (P4D 2018.2+)
- * ham: High Availability metadata-only standby replica, for 'p4 failover' (P4D 2018.2+)
- * ro: Read-Only standby replica. (Discouraged; Use 'ha' instead for 'p4 failover' support.)
- * rom: Read-Only standby replica, Metadata only. (Discouraged; Use 'ham' instead for 'p4 failover' support.)
- * fr: Forwarding Replica (Unfiltered).
- * fs: Forwarding Standby (Unfiltered).
- * frm: Forwarding Replica (Unfiltered, Metadata only).
- * fsm: Forwarding Standby (Unfiltered, Metadata only).
- * ffr: Filtered Forwarding Replica. Not a valid failover target.
- * edge: Edge Server. Filtered by definition.

Replicas with 'standby' are always unfiltered, and use the 'journalcopy' method of replication, which copies a byte-for-byte verbatim journal file rather than one that is merely logically equivalent.

The tag has several purposes:

1. Short Hand. Each tag represents a combination of 'Type:' and fully qualified 'Services:' values used in server specs.
2. Distillation. Only the most useful Type/Services combinations have a shorthand form
3. For forwarding replicas, the name includes the critical distinction of whether any replication filtering is used; as filtering of any kind disqualifies a replica from being a potential failover target. (No such distinction is needed for edge servers, which are filtered by definition).

-s <Site_Tag>

Specify a geographic site tag indicating the location and/or data center where the replica will physically be located. Valid site tags are defined in the site tags file:

```
/p4/common/config/SiteTags.cfg
```

A sample SiteTags.cfg file that is here:

```
/p4/common/config/SiteTags.cfg.sample
```

-r <Replica_Host>

Specify the DNS name of the server machine on which the new replica will run. This is used in the 'ExternalAddress:' field of the replica's ServerID, and also used in instructions to the user for steps after metadata configuration is done by this script.

-f <From_ServerID>

Specify ServerID of the P4TARGET server from which we are replicating.

This is used to populate the 'ReplicatingFrom' field of the server spec. The value must be a valid ServerID.

This option should be used if the target is something other than the master. For example, to create an HA replica of an edge server, you might specify something like '-f p4d_edge_syd'.

-os Specify the '-os' option to overwrite an existing server spec. By default, this script will abort if the server spec to be generated already exists on the Helix Core server. Specify this option to overwrite the existing server spec.

-p This script performs a check to ensure that the Protections table grants super access to the group ServiceUsers.

By default, an error is displayed if the check fails, i.e. if super user access for the group ServiceUsers cannot be verified. This is because, by default, we want to avoid making changes to the Protections table. Some sites have local policies or custom automation that requires site-specific procedures to update the Protections table.

If '-p' is specified, an attempt is made to append the Protections table an entry like:

```
super group ServiceUsers * //...
```

-N <N>

Specify '-N <N>', where N is an integer. This is used to indicate that multiple replicas of the same type are to be created at the same site. The value specified with '-N' must be a numeric value. Left-padding with zeroes is allowed. For example, '-N 04' is allowed, and '-N A7' is not (as it is not numeric).

This affects the ServerID to be generated. For example, the options '-t edge -s syd' would result in a ServerID of p4d_edge_syd. To create a second edge in the same site, use '-t edge -s syd -N 2' to generate p4d_edge2_syd.

-i <SDP_Instance>

Specify the SDP Instance. If not specified and the SDP_INSTANCE environment is defined, that value is used. If SDP_INSTANCE is not defined, the '-i <SDP_Instance>' argument is required.

-v<n> Set verbosity 1-5 (-v1 = quiet, -v5 = highest).

-L <log>

Specify the path to a log file, or the special value 'off' to disable logging. By default, all output (stdout and stderr) goes in the logs directory referenced by \$LOGS environment variable, in a file named mkrep.<timestamp>.log

NOTE: This script is self-logging. That is, output displayed on the screen is simultaneously captured in the log file. Do not run this script with redirection operators like '> log' or '2>&1', and do not use 'tee.'

-n No-Op. Prints commands instead of running them.

-D Set extreme debugging verbosity.

HELP OPTIONS:

-h Display short help message

-man Display man-style help message

-V Display version info for this script and its libraries.

FILES:

This Site Tags file defines the list of valid geographic site tags:
/p4/common/config/SiteTags.cfg

The contains one-line entries of the form:

<tag>: <description>

where <tag> is a short alphanumeric tag name for a geographic location, data center, or other useful distinction. This tag is incorporated into the ServerID of replicas or edge servers created by this script. Tag names should be kept short, ideally no more than about 5 characters in length.

The <description> is a one-line text description of what the tag refers to, which may contain spaces and ASCII punctuation.

Blank lines and lines starting with a '#' are considered comments and are ignored.

REPLICA SERVER MACHINE SETUP:

The replica/edge server machine must have the SDP structure installed, either using the mkdirs.sh script included in the SDP, or the Helix Installer for 'green field' installations.

When setting up an edge server, a replica of an edge server, or filtered replica, confirm that the JournaPrefix Standard (see URL above) structure has the separate checkpoints folder as identified in the 'Second Form' in the standard. A baseline SDP structure can typically be extended by running commands like these samples (assuming a ServerID of p4d_edge_syd or p4d_ha_edge_syd):

```
mkdir /hxdepots/p4/1/checkpoints.edge_syd
cd /p4/1
ln -s /hxdepots/p4/1/checkpoints.edge_syd
```

CUSTOM PRE- AND POST- OPERATION AUTOMATION HOOKS:

This script can execute custom pre- and post- processing scripts. This

can be useful to incorporate site-specific elements of replica setup.

If the file `/p4/common/site/mkrep/pre-mkrep.sh` exists and is executable, it will be executed before `mkrep.sh` processing. If the file `/p4/common/site/mkrep/post-mkrep.sh` exists and is executable, it will be executed after `mkrep.sh` processing.

Pre- and post- processing scripts are called with the same command line arguments passed to this `mkrep.sh` script.

The pre- and post- processing scripts can use or ignore arguments as needed, though it is required to implement the `'-n'` flag to operate in preview mode, taking no actions that affect data (just as this script behaves).

Pre- and post- processing scripts are expected to exit with a zero exit code to indicate success, and non-zero to indicate failure.

The custom pre-processing script is executed after standard preflight checks complete successfully. If a custom pre-processing script indicates a failure, processing is aborted before standard `mkrep.sh` processing occurs.

The post-processing custom script is executed after the standard `mkrep.sh` processing is successful. If a post-processing custom script is detected, the instructions that would be provided to the user in Phase 2 are not displayed, as it is expected that the custom post-processing will alter or handle these steps.

Success or failure of pre- and post- processing scripts is reported in the log. These scripts do not require independent logging, as all standard and error output is captured in the log of this `mkrep.sh` script.

TIP: Be sure to fully test custom scripts in a test environment before incorporating them into production systems.

EXAMPLES:

EXAMPLE 1 - Set up a High Availability (HA) Replica of the master.

Add an HA replica to instance 1 to run on host `bos-helix-02`:
`mkrep.sh -i 1 -t ha -s bos -r bos-helix-02`

EXAMPLE 2 - Add an Edge Server to the topology.

Add an Edge server to instance `acme` to run on host `syd-helix-04`:

`mkrep.sh -i acme -t edge -s syd -r syd-helix-04`

EXAMPLE 3 - Setup an HA replica of an edge server.

```
Add a HA replica of the edge server to instance acme to run on host syd-helix-05:
```

```
mkrep.sh -i acme -t ha -f p4d_edge_syd -s syd -r syd-helix-05
```

EXAMPLE 4 - Add a second edge server in the same site as another edge.

```
mkrep.sh -i acme -t edge -N 2 -s syd -r syd-helix-04
```

9.4.8. p4verify.sh

The `/p4/common/bin/p4verify.sh` script verifies the integrity of the 'archive' files, all versioned files in your repository. This script is run by crontab on a regular basis, typically weekly.

It verifies [both shelves and submitted archive files](#)

Any errors in the log file (e.g. `/p4/1/logs/p4verify.log`) should be handled according to KB articles:

- [MISSING! errors from p4 verify](#)
- [BAD! error from p4 verify](#)

If in doubt contact support-helix-core@perforce.com

Our recommendation is that you should expect this to be without error, and you should address errors sooner rather than later. This may involve obliterating unrecoverable errors.

when run on replicas, this will also append the `-t` flag to the `p4 verify` command to ensure that MISSING files are scheduled for transfer. This is useful to keep replicas (including edge servers) up-to-date.

Usage

```
/p4/common/bin/p4verify.sh <instance>
/p4/common/bin/p4verify.sh 1
```

USAGE for v5.16.0:

```
p4verify.sh [<instance>] [-N] [-nu] [-nr] [-ns] [-nS] [-a] [-nt] [-nz] [-o
BAD|MISSING] [-chunks <ChunkSize>|-paths <paths_file>] [-w <Wait>] [-q
<MaxActivePullQueueSize>] [-Q MaxTotalPullQueueSize] [-recent | -recent=N] [-dlf
<depot_list_file>] [-I|-ignores <regex_ignores_file>] [-Ocache] [-n] [-L <log>] [-v]
[-d] [-D]
```

or

```
p4verify.sh -h|-man
```

DESCRIPTION:

This script performs a 'p4 verify' of all submitted and shelved versioned files in depots of all types except 'remote' and 'archive' type depots.

The singular Extensions depot is also verified, if present.

The singular Traits depot is also verified, if present.

Archive depots are not verified by default, but can be with the '-a' option.

If run on a replica, it schedules archive failures for transfer to the replica.

OPTIONS:

<instance>

Specify the SDP instance. If not specified, the SDP_INSTANCE environment variable is used instead. If the instance is not defined by a parameter and SDP_INSTANCE is not defined, p4verify.sh exists immediately with an error message.

-N Specify '-N' (Notify Only On Failure) to disable the default behavior which will always send a notification which includes a report of the p4 verify status. Specifying '-N' which change the behavior to only send a notification if there is an error during the p4 verify execution. Notification methods are email, AWS SNS, and PagerDuty. Details on configuration can be found in the SDP documentation. Providing the environment variable NOTIFY_ONLY_ON_FAILURE=1 is equivalent to the '-N' command line argument.

-nu Specify '-nu' (No Unload) to skip verification of the singleton depot of type 'unload' (if created). The 'unload' depot is verified by default.

-nr Specify '-nr' (No Regular) to skip verification of regular submitted archive files. The '-nr' option is not compatible with '-recent'. Regular submitted archive files are verified by default.

This option also causes Extension and Traits depots (if present) not to be verified.

-ns Specify '-ns' (No Spec Depot) to skip verification of singleton depot of type 'spec' (if created). The 'spec' depot is verified by default.

-nS Specify '-nS' (No Shelves) to skip verification of shelved archive files, i.e. to skip the 'p4 verify -qS'.

-a Specify '-a' (Archive Depots) to do verification of depots of type 'archive'. Depots of type 'archive' are not verified by default, as archive depots are often physically removed from the server's storage subsystem for long-term cold storage.

- `-nt` Specify the `'-nt'` option to avoid passing the `'-t'` flag to `'p4 verify'` on a replica. By default, `p4verify.sh` detects if it is running on a replica, and if so automatically applies the `'-t'` flag to `'p4 verify'`. That causes the replica to attempt to self-heal, as files that fail verification are scheduled for transfer from the `P4TARGET` server. This default behavior results in `'Transfer scheduled'` messages in the log, and `MISSING/BAD` files are listed as `'info:'` rather than `'error:'`. There is no clear indication of whether or which of the scheduled transfers complete successfully, and so there may be a mix of transient/correctable and "real"/persistent transfer errors for files that are also `BAD/MISSING` on the master server. Specify `'-nt'` to ensure the log contains a list of files that currently fail a `'p4 verify'` without attempting to transfer them from the master.
- `-nz` Specify `'-nt'` to skip the gzip of the old log file. By default, if a log with the default name or the name specified with `'-L'` exists at the start of processing, the old log is rotated and gzipped. With this option the old log is not zipped when rotated.
- `-o BAD|MISSING`
Specify `'-o MISSING'` to check only whether expected archive files exist or not, skipping the checksum calculation of existing files. This results in dramatically faster, if less comprehensive, verification. This is particularly well suited when verification is being used to schedule archive file transfers of missing files on replicas. This translates into passing the `'--only MISSING'` option to `'p4 verify'`.
- Specify `'-o BAD'` to check only for `BAD` revisions. This translates into passing the `'--only BAD'` option to `'p4 verify'`.
- This option requires `p4d` to be 2021.1 or newer. For older `p4d` versions, this option is silently ignored.
- `-chunks <ChunkSize>`
Specify the maximum amount of content by size to verify at once. If this is specified, the `depot_verify_chunks.py` script is used to break up depots into chunks of a given size, e.g. `100M` or `4G`.
- The `<ChunkSize>` parameter must be a size value valid to pass to the `depot_verify_chunks.py` script with the `'-m'` option. That is, specifying `'-chunks 200M'` translates to calling `depot_chunks_verify.sh` with `'-m 200M'`.
- This requires the `perforce-p4python3` module to be installed and the `python3` in the `PATH` must be the correct one that uses the `P4` module.
- Using `'-chunks'` is likely to result in a significantly slower overall verify operation, though chunking can make it less impactful when it runs. Using the `'-chunks'` option may be necessary on very large data sets, e.g. if there insufficient resources to process the largest depots.

The '-recent' and '-chunks' options are mutually exclusive.

The '-chunks' and '-paths' options can be used together; see the description of the '-paths' option below.

Chunking logic applies only in depots of type 'stream' or 'local'.

`-paths <paths_file>`

Specify a file containing a list of depot paths to verify, with one line per entry. Valid entries in the file start with '//', e.g.

```
//mydepot/main/src/...
```

In this example, when //mydepot depot is processed, only specified paths will be verified. All other depots will be processed in full. To verify only specified paths, combine '-paths <paths_file>' with '-dlf <depot_list_file>' where the depot list file contains only 'mydepot' (per the example above).

The '-chunks' and '-paths' options can be used together for combined effects. If both options are specified, depots that contain specified paths are chunked based on the specified paths rather than the entire depot, and other paths in that depot are not processed. Depots that do not have any specified paths listed in the <paths_file> are chunked at the top/depot level directory.

The '-paths' option can be combined with '-recent' to verify only recent changelists in the specified paths.

This option disables processing of the Extensions and Traits depots by default, though '-paths' can specify paths in those depots.

Paths specified must be in depots of type 'stream' or 'local', or the singular Extensions or Traits depots.

`-w <Wait>`

Specify the '-w' option, where <Wait> is a positive integer indicating the number of seconds to sleep between individual calls to 'p4 verify' commands. For example, specifying '-w 300' results in a delay of 5 minutes between verify commands.

This can be used with '-chunks' to inject a delay between chunked depot paths. Otherwise, the delay is injected between each depot processed. This can significantly lengthen the overall duration of 'p4verify.sh' operation, but can also spread out the resource consumption load on a server machine.

If shelves are processed (regardless of whether '-chunks' is used), the delay is injected between each individual shelved changelist, as

shelved changes are verified one changelist at a time. For data sets with a large number of shelves, it may be wise to process shelves separately from submitted files if '-w' is used, a delay value to apply between depots may be different from that applied to individual changelists.

See the '-q' option for a description of how '-q' and '-w' can be used together.

-q <MaxActivePullQueueSize>

Specify the '-q' option, where <MaxActivePullQueueSize> is a positive integer indicating the maximum number of active pulls allowed before a 'p4 verify' command will be executed to transfer archives.

The absolute maximum number of possible active pulls is affected by the number of 'startup.N' threads configured to pull archive files, and whether those threads indicate batching.

The threads that pull archive files are those that configured to use the 'pull' command the '-u' option. Typically, a small number of pull threads are configured, between 2 and 10 or perhaps 20.

If '-q 1' is specified, new 'p4 verify' commands will only be run when the active pull queue is quiet. Specifying a too-high value, e.g. '-q 50' if only 3 'pull -u' archive pull threads are configured, will be ineffective, as the active pull threads will never exceed 3 (let alone 50).

The current active pull queue on a replica is reported by:

```
p4 -ztag -F %replicaTransfersActive% pull -ls
```

This option can be useful if using this p4verify.sh script to pull many or even all archives on a new replica server machine from its target server. The injected delays can give the server time to transfer archives scheduled in one call to 'p4 verify' before calling it again with the goal of avoiding overloading the pull queue.

If '-w' and '-q' options are both used, the delay specified by '-w' is ignored unless the active pull queue size is greater than or equal to the specified maximum active pull queue size. The '-w' then essentially determines how frequently the 'p4 pull -ls' is run to check the active pull queue size. A reasonable set of values might be '-q 1 -w 10'.

The '-q' option is mutually exclusive with '-nt'.

The '-q' option is mutually exclusive with '-Q'.

-Q <MaxTotalPullQueueSize>

Specify the '-Q' option, where <MaxTotalPullQueueSize> is a positive

integer indicating the maximum number of total pulls allowed before a 'p4 verify' command will be executed to transfer archives.

In certain scenarios, the pull queue can become quite massive. For example, if a fresh standby replica is seeded from a checkpoint but has no archive files, and then a 'p4verify.sh' is run, the verify will schedule all files to be transferred, perhaps millions.

If the pull queue gets too large, it can impact metadata replication. Setting this value may help mitigate issues related to scheduling too many archives pulls at once, by delaying scheduling new archive pulls until enough previously scheduled pulls are completed.

This option can be useful in such scenarios, if this p4verify.sh script is used to pull many or even all archives on a new replica server machine from its target server. The injected delays can give the server time to transfer archives scheduled in one call to 'p4 verify' before calling it again with the goal of avoiding overloading the pull queue.

If individual depots contain large numbers of files, such that a verify on a single depot will schedule too many files to be transferred at once, it may be necessary to combine this option with the '-chunks' option to avoid overloading the transfer queue.

****WARNING****: If there are files that cannot be transferred from the replica's target server, the value of '-Q' must be set to higher than that number, or an infinite loop may occur. For example, if there are 500 permanent "legacy" verify errors on the commit server from 10 years ago that have long since been abandoned, those files can never be transferred to any replica. Running p4verify.sh on the replica will cause those files to be scheduled, but as they cannot be pulled, they will land in the total pull queue. In this scenario, the value set with '-Q' must be greater than 500, or an infinite loop is possible.

Specify '-Q 0' to disable checking the total pull queue.

The current total pull queue on a replica is reported by:

```
p4 -ztag -F %replicaTransfersTotal% pull -ls
```

This option can be useful if using this p4verify.sh script to pull many or even all archives on a new replica server machine from its target server. The injected delays can give the server time to transfer archives scheduled in one call to 'p4 verify' before calling it again with the goal of avoiding overloading the pull queue.

If '-w' and '-Q' options are both used, the delay specified by '-w' is ignored unless the total pull queue size is greater than or equal to the specified maximum total pull queue size. The '-w' then essentially determines how frequently the 'p4 pull -ls' is run to check the total pull queue size. A reasonable set of values might

be '-q 50000 -w 10'.

The '-Q' option is mutually exclusive with '-nt'.

The '-Q' option is mutually exclusive with '-q'.

-recent[=N]

Specify that only recent changelists should be verified.

This can be specified as '-recent' or '-recent=N', where N is an integer indicating the number of recent changelists to verify.

If '-recent' is used without the optional '=N' syntax, the \$SDP_RECENT_CHANGES_TO_VERIFY variable defines how many changelists are considered recent; the default is 200.

If the default is not appropriate for your site, add "export SDP_RECENT_CHANGES_TO_VERIFY" to /p4/common/site/config/p4_N.vars.local to change the default for an instance, or to /p4/common/site/config/p4_vars.local to change it globally. If \$SDP_RECENT_CHANGES_TO_VERIFY is unset, the default is 200.

When -recent is used, files in the unload depot are not verified.

-dlf <depot_list_file>

Specify a file containing a list of depots to process in the desired order. By default, all depots in the order reported by reported by 'p4 depots' are processed, which effectively results in depots being processed in alphabetical order, with the singleton Extensions and Traits depots (if present) being processed after other depots.

This '-dlf' option can be useful in time-sensitive situations where the order of processing can be prioritized, and/or to prevent processing certain depots.

The format for the depot list file is straightforward, one line per depot, without the '// ' nor trailing /... , so a list might look like this sample:

```
ProjA
ProjB
spec
.swarm
unload
archive
ProjC
```

Blank lines and lines starting with a '#' are treated as comments and ignored.

WARNING: This is not intended to be the primary method of verification,

because it would be easy to forget to add new depots to the list file.

If the depot list file is not readable, processing aborts.

This option disables processing of the singleton Extensions and Traits depots unless those depots are explicitly included in the depot list file.

`-ignores <regex_ignores_file>`

Specify the 'verify ignores' file, a file containing a series of regular expression patterns representing files or file revisions to ignore when scanning for verify errors. Errors matching the pattern will be suppressed from the output captured in the log, and will not be considered a verification error.

If the '-ignores' is not specified, the default verify ignores file is:

```
/p4/common/config/p4verify.N.ignores
```

where 'N' is the SDP instance name. If this file exists, it is considered the 'verify ignores' file.

Specify '-ignores none' to avoid processing the standard ignores file.

The patterns can be specific files, specific file paths, or broader patterns (e.g. in the case of entirely abandoned depots). The file provided is passed as the '-f <file>' option to the 'grep' utility, and is expected to contain a series of one-line entries, each containing an expression to exclude from being considered as verify errors reported by this script.

You can test your expression by first using it with grep to ensure it suppresses errors by using a command like this sample, providing an older log from this script that contains errors to be suppressed:

```
grep -Ev -f /path/to/regex_file /path/to/old/p4verify.log
```

If your server is case-sensitive, change that command to use '-i':

```
grep -Evi -f /path/to/regex_file /path/to/old/p4verify.log
```

This sample entry ignores a single file revision:

```
//Alpha/main/docs/Expenses from February 1999.xls#3
```

This sample entry ignores all revisions of a single file:

```
//Alpha/main/docs/Expenses from February 1999.xls
```

This sample entry ignores all entries in the spec depot related to client specs:

```
//spec/client
```

This sample uses the MD5 checksum from the verify error, just to illustrate that this can be used as an alternative to specifying file paths:

```
D34989BFB8D9B0FB9866C4A604A05410
```

This sample ignores BAD! (but not MISSING!) errors under the //Beta/main/src directory tree:

```
//Beta/main/src/. * BAD!
```

WARNING: Ensure that the regex file provided does NOT contain any blank lines or comments. The file should contain only tested regex patterns.

This option is intended to provide a way to ignore unrecoverably lost file revisions from things like past infrastructure failures, for which search and recovery efforts have been abandoned. This option subtly changes the question answered by this script from "Are there any verify errors?" to "Are there any new verify errors, errors we don't already know about?"

WARNING: This option is not intended to be incorporated into the primary method of verification, because ignoring archive errors in this script does not solve the problem at its source. Ideally, the root cause of the verify errors should be addressed by recovering lost archives, injecting replacement content, or other means. So long as verify errors remain, even if ignored by this option, users attempting to access the revisions will still see Librarian errors, and replicas will encounter errors trying to pull the missing archives. This option could increase the risk that such revisions are never dealt with.

-Ocache

Specify '-Ocache' to attempt a verification on a replica configured with a 'lbr.replication' replication configuration setting value of 'cache'. By default, if the 'lbr.replication' configurable is set to 'cache', this script aborts, as replication of such a depot will schedule transfers that are likely unintended. This is a safety feature.

The 'cache' mode is generally used on replicas or edge servers with limited disk space. Because running a verify will cause transfers of any missing files, this could result in filling up the disk.

Use of '-Ocache' is strongly discouraged unless combined with

other options to ensure that only targeted paths are scheduled for transfer.

- v Verbose. Show output of verify attempts, which is suppressed by default. Setting `SDP_SHOW_LOG=1` in the shell environment has the same effect as `-v`.

The default behavior of this script is to generate no terminal output, but instead to write output into a log file -- see LOGGING below. If `'-v'` is specified, the generated log is sent to stdout at the end of processing. This flag is not recommended for routine cron operation or for large data sets.

The `-chunks` and `-recent` options are mutually exclusive.

- L <log>
Specify the log file to use. The default is `/p4/N/logs/p4verify.log`

Log rotation and old log cleanup logic does not apply to log files specified with `-L`. Thus, using `-L` is not recommended for routine scheduled operation, e.g. via crontab.

DEBUGGING OPTIONS:

- n No-Operation (NO_OP) mode, for debugging.

Display certain commands that would be executed without executing them. When `'-n'` is used, commands that might take a long time to run or affect data are only displayed.

Even in `'-n'` mode, some information-gathering commands such as listing shelved CLs are executed, which may cause the script to take a bit of time to run on a large data set even in dry run mode.

- d Specify that debug messages should be displayed.
- D Use bash `'set -x'` extreme debugging verbosity, and imply `'-d'`.

- L off
The special value `'-L off'` disables logging. This can only be used with `'-n'` for debugging.

HELP OPTIONS:

- h Display short help message
- man Display man-style help message

EXAMPLES:

Example 1: Full Verify

This script is typically called via cron with only the instance parameter as an argument, e.g.:

```
p4verify.sh 1
```

Example 2: Fast Verify

A "fast" verify is one in which only the check for MISSING archives is done, while the resource-intensive checksum calculation of potentially BAD existing archives is skipped. This is especially useful when used on a replica.

```
p4verify.sh 1 -o MISSING
```

Example 3: Fast and Recent Verify

The '-o MISSING' and '-recent' flags can be combined for a very fast check. This check might be incorporated into a failover procedure.

```
p4verify.sh 1 -o MISSING -recent
```

Example 4: Submitted Files Only

This will verify only use submitted files, ignoring shelves and the spec and unload depots, putting the results in a specified log:

```
p4verify.sh 1 -ns -nS -nu -L -L /p4/1/logs/p4verify.submitted.log
```

Example 5: Shelved Files Only

This will verify only use submitted files, ignoring shelves and the spec and unload depots, putting them in a specified log:

```
p4verify.sh 1 -nr -ns -nu -L /p4/1/logs/p4verify.shelved.log
```

Example 6: A Dry Run

The '-n' option can be used for a dry run. Output may also be displayed to the screen ('-v') for a dry run and the log file optionally discarded:

```
p4verify.sh 1 -n -nS -L off -v
```

Example 7: Archive File Load for New Replica

The p4verify.sh script can be used to schedule transfers of a large number of files from a replica. When doing so, however, overloading the new replicas pull queue with too many files may impact metadata replication. This can be addressed by combining a variety of options, such as '-chunks' and '-Q'. For example:

```
p4verify.sh 1 -chunks 200M -Q 10000 -w 20 -o MISSING
```

NOHUP USAGE:

Because archive verification is typically a long running task, it is advisable to use 'nohup' to call each command, and combine that by running the command as a background process. Alternately, use 'screen' or similar.

Any of the examples above can be used with 'nohup', without output redirected to /dev/null (i.e. to "the void", as this script handles logging and output redirection).

To use 'nohup', start the command line with 'nohup', and then after the command, add this text exactly:

```
< /dev/null > /dev/null 2>&1 &
```

As a example, Example 2 above, called with nohup, would look like:

```
nohup /p4/common/bin/p4verify.sh 1 -o MISSING < /dev/null > /dev/null 2>&1 &
```

With the ampersand '&' at the end, the command will appear to return immediately as the process continues to run in the background.

Then optionally monitor the log:

```
tail -f /p4/1/logs/p4verify.log
```

LOGGING:

This script generates no output by default. All (stdout and stderr) is logged to /p4/N/logs/p4verify.log.

The exception is usage errors, which result an error being sent to stderr followed usage info on stdout, followed by an immediate exit.

NOTIFICATIONS:

In addition to logging, a short summary of the verify is sent as a notification. The summary is reliably short even if the output of the verifications done by this script results in a large log file.

There are two notification schemes with this script:

- * Email notification is always attempted.

- * AWS SNS notification is attempted if the SNS_ALERT_TOPIC_ARN custom setting is defined. This is typically set in:

```
/p4/common/site/config/p4_N.vars.local
```

TIMING:

The log file captures various timing information, including the time required to verify each depot, or each chunk or path if '-paths' or '-chunks' are used. The time to verify shelves in all depots is reported separately from submitted files.

Timing indications all start with the text 'Time: ' on the beginning of a line of output in the log file, and can be extracted with a command like this example (adjusting the log file name as needed):

```
grep ^Time: /p4/1/logs/p4verify.log
```

EXIT CODES:

An exit code of 0 indicates no errors were encountered attempting to perform verifications, AND that all verifications attempted reported no problems.

A exit status of 1 indicates that verifications could not be attempted for some reason.

A exit status of 2 indicates that verifications were successfully performed, but that problems such as BAD or MISSING files were detected, or else system limits prevented verification.

9.4.9. p4login

The `/p4/common/bin/p4login` script is a convenience wrapper to execute a series of `p4 login` commands, using the administration password configured in `mkdirs.cfg` and subsequently stored in a text file: `/p4/common/config/.p4passwd .p4_<instance>.admin`.

Usage

USAGE for p4login v4.4.4:

```
p4login [<instance>] [-p <port> | -service] [-automation] [-all]
```

or

```
p4login -h|-man
```

DESCRIPTION:

In its simplest form, this script simply logs in P4USER to P4PORT using the defined password access mechanism.

It generates a login ticket for the SDP super user, defined by P4USER when sourcing the SDP standard shell environment. It is called from cron scripts, and so does not normally generate any output.

If run on a replica with the `-service` option, the `serviceUser` defined for the given replica is logged in.

The `$SDP_AUTOMATION_USERS` variable can be defined in `/p4/common/config/p4_N.vars`. If defined, this should contain a

comma-delimited list of automation users to be logged in when the `-automation` option is used. A definition might look like:

```
export SDP_AUTOMATION_USERS=builder,trigger-admin,p4review
```

Login behavior is affected by external factors:

1. `P4AUTH`, if defined, affects login behavior on replicas.
2. The `auth.id` setting, if defined, affects login behaviors (and generally simplifies them).
3. The `$SDP_ALWAYS_LOGIN` variable. If set to 1, this causes `p4login` to always execute a 'p4 login' command to generate a login ticket, even if a 'p4 login -s' test indicates none is needed. By default, the login is skipped if a 'p4 login -s' test indicates a long-term ticket is available that expires 31+days in the future. Add "export SDP_ALWAYS_LOGIN=1" to `/p4/common/config/p4_N.vars` to change the default for an instance, or to `/p4/common/bin/p4_vars` to change it globally. If unset, the default is 0.
4. If the `P4PORT` contains an `ssl:` prefix, the `P4TRUST` relationship is checked, and if necessary, a `p4 trust -f -y` is done to establish trust.

OPTIONS:

`<instance>`

Specify the SDP instances. If not specified, the `SDP_INSTANCE` environment variable is used instead. If the instance is not defined by a parameter and `SDP_INSTANCE` is not defined, `p4login` exists immediately with an error message.

`-service`

Specify `-service` when run on a replica or edge server to login the super user and the replication service user.

This option is not compatible with '`-p <port>`'.

`-p <port>`

Specify a `P4PORT` value to login to, overriding the default defined by `P4PORT` setting in the environment. If operating on a host other than the master, and `auth.id` is set, this flag is ignored; the `P4TARGET` for the replica is used instead.

This option is not compatible with '`-service`'.

`-automation`

Specify `-automation` to login external automation users defined by the `$SDP_AUTOMATION_USERS` variable.

`-v` Show output of login attempts, which is suppressed by default.

Setting `SDP_SHOW_LOG=1` in the shell environment has the same effect as `-v`.

`-L <log>`

Specify the log file to use. The default is `/p4/N/logs/p4login.log`

`-d` Set debugging verbosity.

`-D` Set extreme debugging verbosity.

HELP OPTIONS:

`-h` Display short help message

`-man` Display man-style help message

EXAMPLES:

1. Typical usage for automation, with instance `SDP_INSTANCE` defined in the environment by sourcing `p4_vars`, and logging in only the super user `P4USER` to `P4PORT`:

```
source /p4/common/bin/p4_vars abc
p4login
```

Login in only `P4USER` to the specified port, `P4MASTERPORT` in this example:

```
p4login -p $P4MASTERPORT
```

Login the super user `P4USER`, and then login the replication serviceUser for the current `ServerID`:

```
p4login -service
```

Login external automation users (see `SDP_AUTOMATION_USERS` above):

```
p4login -automation
```

Login all users:

```
p4login -all
```

Or: `p4login -service -automation`

LOGGING:

This script generates no output by default. All (stdout and stderr) is logged to `/p4/N/logs/p4login.log`.

The exception is usage errors, which result an error being sent to stderr followed usage info on stdout, followed by an immediate exit.

If the `'-v'` flag is used, the contents of the log are displayed to stdout at the end of processing.

EXIT CODES:

An exit code of `0` indicates a valid login ticket exists, while a non-zero exit code indicates a failure to login.

9.4.10. p4d_<instance>_init

Starts the Perforce server instance. Can be called directly or as describe in [Section 5.1.3](#), “[Configuring Automatic Service Start on Boot](#)” - it is created by `mkdirs.sh` when SDP is installed.

Do not use directly if you have configured `systemctl` for `systemd` Linux distributions such as CentOS 7.x. This risks database corruption if `systemd` does not think the service is running when it actually is running (for example on shutdown `systemd` will just kill processes without waiting for them).

This script sources `/p4/common/bin/p4_vars`, then runs `/p4/common/bin/p4d_base` ([Section 9.6.12](#), “[p4d_base](#)”).

Usage

```
/p4/<instance>/bin/p4d_<instance>_init [ start | stop | status | restart ]
/p4/1/bin/p4d_1_init start
```

9.4.11. recreate_offline_db.sh

The `/p4/common/bin/recreate_offline_db.sh` recovers the `offline_db` database from the latest checkpoint and replays any journals since then. If you have a problem with the offline database then it is worth running this script first before running [Section 9.4.6](#), “[live_checkpoint.sh](#)”, as the latter will stop the server while it is running, which can take hours for a large installation.

Run this script if an error occurs while replaying a journal during daily checkpoint process.

This script recreates `offline_db` files from the latest checkpoint. If it fails, then check to see if the most recent checkpoint in the `/p4/<instance>/checkpoints` directory is bad (ie doesn’t look like the right size compared to the others), and if so, delete it and rerun this script. If the error you are getting is that the journal replay failed, then the only option may be to run [Section 9.4.6](#), “[live_checkpoint.sh](#)” script.

Usage

```
/p4/common/bin/recreate_offline_db.sh <instance>
/p4/common/bin/recreate_offline_db.sh 1
```

9.4.12. refresh_P4ROOT_from_offline_db.sh

The `/p4/common/bin/refresh_P4ROOT_from_offline_db.sh` script is intended to be used occasionally, perhaps monthly, quarterly, or on-demand, to help ensure that your live (`root`) database files are defragmented.

It will:

- stop `p4d`
- truncate/rotate live journal

- replay journals to `offline_db`
- switch the links between `root` and `offline_db`
- restart `p4d`

It also knows how to do similar processes on edge servers and standby servers or other replicas.

Usage

```
/p4/common/bin/refresh_P4ROOT_from_offline_db.sh <instance>
/p4/common/bin/refresh_P4ROOT_from_offline_db.sh 1
```

9.4.13. `run_if_master.sh`

The `/p4/common/bin/run_if_master.sh` script is explained in [Section 9.4.16, “run_if_master/edge/replica.sh”](#)

9.4.14. `run_if_edge.sh`

The `/p4/common/bin/run_if_edge.sh` script is explained in [Section 9.4.16, “run_if_master/edge/replica.sh”](#)

9.4.15. `run_if_replica.sh`

The `/p4/common/bin/run_if_replica.sh` script is explained in [Section 9.4.16, “run_if_master/edge/replica.sh”](#)

9.4.16. `run_if_master/edge/replica.sh`

The SDP uses wrapper scripts in the crontab: `run_if_master.sh`, `run_if_edge.sh`, `run_if_replica.sh`. We suggest you ensure these are working as desired, e.g.

Usage

```
/p4/common/bin/run_if_master.sh 1 echo yes
/p4/common/bin/run_if_replica.sh 1 echo yes
/p4/common/bin/run_if_edge.sh 1 echo yes
```

It is important to ensure these are returning the valid results for the server machine you are on.

Any issues with these scripts are likely configuration issues with `/p4/common/config/p4_1.vars` (for instance `1`)

9.4.17. `sdp_health_check.sh`

This script is described in the appendix [Appendix H, SDP Health Checks](#).

```
USAGE for sdp_health_check.sh v1.9.0:
```

```
sdp_health_check.sh
```

or

```
sdp_health_check.sh -h|-man
```

DESCRIPTION:

This script does a health check of the SDP. It generates a report log, which can be emailed to support@perforce.com. It identifies SDP instances and reports on general SDP health.

It must be run as the OS user who owns the /p4/common/bin directory. This should be the user account which runs the p4d process, and which owns the /p4/common/bin directory (often 'perforce' or 'p4admin').

Characteristics of this script:

- * It is always safe to run. It does only analysis and reporting.
- * It does only fast checks, and has no interactive prompts. Some log files are captured such as checkpoint.log, but not potentially large ones such as the p4d server log.
- * It requires no command line arguments.
- * It works for any and all UNIX/Linux SDP version since 2007.

Assumptions:

- * The SDP has always used /p4/common/bin/p4_vars as the shell environment file. This is consistent across all SDP versions.

OPTIONS:

-D Set extreme debugging verbosity.

HELP OPTIONS:

-h Display short help message
-man Display man-style help message

EXAMPLES:

This script is typically called with no arguments.

LOGGING:

This script generates a log file and also displays it to stdout at the end of processing. By default, the log is:

```
/tmp/sdp_health_check.<datestamp>.log
```

or

```
/tmp/sdp_health_check.log
```

The exception is usage errors, which result an error being sent to

```
stderr followed usage info on stdout, followed by an immediate exit.
```

EXIT CODES:

```
An exit code of 0 indicates no errors or warnings were encountered.
```

9.5. More Server Scripts

These scripts are helpful components of the SDP that run on the server machine, but are not included in the default crontab schedules.

9.5.1. p4.crontab

Contains crontab entries to run the server maintenance scripts.

Location: `/p4/sdp/Server/Unix/p4/common/etc/cron.d`

9.5.2. verify_sdp.sh

The `/p4/common/bin/verify_sdp.sh` does basic verification of SDP setup.

Usage

```
USAGE for verify_sdp.sh v5.24.0:
```

```
verify_sdp.sh [<instance>] [-online] [-skip <test>[,<test2>,...]] [-warn  
<test>[,<test2>,...]] [-c] [-si] [-L <log>|off ] [-D]
```

or

```
verify_sdp.sh -h|-man
```

DESCRIPTION:

This script verifies the current SDP setup for the specified instance, and also performs basic health checks of configured servers.

This uses the SDP instance bin directory `/p4/N/bin` to determine what server binaries (p4d, p4broker, p4p) are expected to be configured on this machine.

Existence of the `'*_init'` script indicates the given binary is expected. For example, for instance 1, if `/p4/1/bin/p4d_1_init` exists, a p4d server is expected to run on this machine.

Checks may be executed or skipped depending on what servers are configured. For example, if a p4d is configured, the `$P4ROOT/server.id` file should exist. If p4p is configured, the `'cache'` directory should exist.

OPTIONS:

`<instance>`

Specify the SDP instances. If not specified, the `SDP_INSTANCE` environment variable is used instead. If the instance is not defined by a parameter and `SDP_INSTANCE` is not defined, exits immediately with an error message.

`-online`

Online mode. Does additional checks that expect `p4d`, `p4broker`, and/or `p4p` to be online. Any servers for which there are `*_init` scripts in the Instance Bin directory are checked. An error is reported if `p4d` is expected to be online and is not; warnings are displayed if `p4broker` or `p4p` are not online. The Instance Bin directory is the `/p4/N/bin` directory, where `N` is the SDP instance name.

`-c` Specify `'-c'` to call `ccheck.sh` to compare configurables, using the default config file: `/p4/common/config/configurables.cfg`

See `'ccheck.sh -man'` for more information.

This option can only be used in Online mode; if `'-c'` is specified, `'-online'` is implied.

`-skip <test>[,<test2>,...]`

Specify a comma-delimited list of named tests to skip.

Valid test names are:

- * `cron|crontab`: Skip crontab check. Use this if you do not expect crontab to be configured, perhaps if you use a different scheduler.
- * `excess`: Skip checks for excess copies of `p4d/p4p/p4broker` in `PATH`.
- * `init`: Skip compare of init scripts w/templates in `/p4/common/etc/init.d`
- * `license`: Skip license related checks.
- * `masterid`: Skip check ensuring ServerID of master starts with `'master'`.
- * `offline_db`: Skip checks that require a healthy `offline_db`.
- * `p4root`: Skip checks that require healthy `P4ROOT` db files.
- * `p4t_files`: Skip checks for existence of `P4TICKETS` and `P4TRUST` files.
- * `passwd|password`: Skip SDP password checks.
- * `version`: Skip version checks.

As an alternative to using the `'-skip'` option, the shell environment variable `VERIFY_SDP_SKIP_TEST_LIST` can be set to a comma-separated list of named tests to skip. Using the command line parameter is the best choice for temporarily skipping tests, while specifying the environment variable is better for making permanent exceptions (e.g. always excluding the crontab check if crontabs are not used at this site). The variable should be set in `/p4/common/config/p4_N.vars`.

If the `'-skip'` option is provided, the `VERIFY_SDP_SKIP_TEST_LIST` variable is ignored (not appended to). So it may make sense to

reference the variable on the command line. For example, if the value of the variable is 'crontab', to skip crontab and license checks, you could specify:

```
-skip $VERIFY_SDP_SKIP_TEST_LIST,license
```

```
-warn <test>[,<test2>,...]
```

Specify a comma-delimited list of named tests that will be reported as warnings rather than errors.

The list of valid test names as the same as for the '-skip' option.

As an alternative to using the '-warn' option, the shell environment variable `VERIFY_SDP_WARN_TEST_LIST` can be set to a comma-separated list of name tests to skip. Using the command line parameter is the best choice for temporarily converting errors to warnings, while specifying the environment variable is better for making the conversion to warnings permanent. The variable should be set in `/p4/common/config/p4_N.vars` file.

If the '-warn' option is provided, the `VERIFY_SDP_WARN_TEST_LIST` variable is ignored (not appended to). So it may make sense to reference the variable on the command line. For example, if the value of the variable is 'crontab', to convert to warnings for crontab and excess binaries tests, you could specify:

```
-warn $VERIFY_SDP_WARN_TEST_LIST,excess
```

```
-si    Silent mode, useful for cron operation. Both stdout and stderr
       are still captured in the log. The '-si' option cannot be used
       with '-L off'.
```

```
-L <log>
```

Specify the log file to use. The default is `/p4/N/logs/verify_sdp.log`. The special value 'off' disables logging to a file.

Note that '-L off' and '-si' are mutually exclusive.

```
-D Set extreme debugging verbosity.
```

HELP OPTIONS:

```
-h Display short help message
-man Display man-style help message
```

EXAMPLES:

Example 1: Typical usage:

This script is typically called after SDP update with only the instance name or number as an argument, e.g.:

```
verify_sdp.sh 1
```

Example 2: Skipping some checks.

```
verify_sdp.sh 1 -skip crontab
```

Example 3: Automation Usage

If used from automation already doing its own logging, use `-L off`:

```
verify_sdp.sh 1 -L off
```

LOGGING:

This script generates a log file and also displays it to stdout at the end of processing. By default, the log is:
/p4/N/logs/verify_sdp.log.

The exception is usage errors, which result an error being sent to stderr followed usage info on stdout, followed by an immediate exit.

If the `'-si'` (silent) flag is used, the log is generated, but its contents are not displayed to stdout at the end of processing.

EXIT CODES:

An exit code of 0 indicates no errors were encountered attempting to perform verifications, and that all checks verified cleanly.

9.6. Other Scripts and Files

The following table describes other files in the SDP distribution. These files are usually not invoked directly by you; rather, they are invoked by higher-level scripts.

9.6.1. backup_functions.sh

The `/p4/common/bin/backup_functions.sh` script contains Bash functions used in other SDP scripts.

It is **sourced** (`source /p4/common/bin/backup_functions.sh`) by other scripts that use the common shared functions.

It is not intended to be called directly by the user.

9.6.2. broker_rotate.sh

The `/p4/common/bin/broker_rotate.sh` rotates the broker log file. It is intended for use on a server machine that has only broker running. When a broker is run on a p4d server machine, the `daily_checkpoint.sh` take care of rotating the broker log.

It can be added to a crontab for e.g. daily log rotation.

Usage

```
/p4/common/bin/broker_rotate.sh <instance>
/p4/common/bin/broker_rotate.sh 1
```

9.6.3. ccheck.sh

The script `/p4/common/bin/ccheck.sh` script compares configurables against a set of defined best practices.

Usage

USAGE for ccheck.sh v1.0.5:

```
ccheck.sh [<SDPInstance>] [-p <Profile>] [-c <CfgFile>] [-y] [-v] [-d|-D]
```

or

```
ccheck.sh [-h|-man|-V]
```

DESCRIPTION:

This script compares configurables set on the current server with best practices defined a data file.

OPTIONS:

`-p <Profile>`

Specify a profile defined in the config file, such as 'demp' or 'prod'. A profile defines a set of expected configurable values that can differ from the expected values in other profiles. For example, for a demo environment, the

`fileSYS.P4ROOT.min`

might have an expected value of 128M, while the expected value in a prod

(production)

profile might be 5G.

There is a default profile which always applies whether '-p' is specified or not.

The profile specified with '-p' applies in addition to the default configuration.

`-c <CfgFile>`

Specify an alternate config file that defines best practice configurables. This is intended for testing.

`-L <log>`

Specify the path to a log file, or the special value 'off' to disable logging. By default, all output (stdout and stderr) goes to `$LOGS/ccheck.log`

NOTE: This script is self-logging. That is, output displayed on the screen is simultaneously captured in the log file. Using redirection operators like

'> log' or '2>&1' are unnecessary, nor is using 'tee'.

-y Live operation mode. By default, any commands that affect data, such as setting configurables, are displayed, but not executed. With the '-y' option, commands may be executed.

-d Display debug messages.

-D Set extreme debugging verbosity using bash 'set -x' mode. Implies -d.

-si Silient Mode. No output is displayed to the terminal (except for usage errors on startup). Output is captured in the log. The '-si' cannot be used with '-L off'.

HELP OPTIONS:

-h Display short help message

-man Display man-style help message

FILES:

The standard configurables config file is:

/p4/common/config/configurables.cfg

EXAMPLES:

Example 1: Check configurables with the default profile, and no logging:

```
ccheck.sh -L off
```

Example 2: Check configurables with the 'prod' (Production) profile:

```
ccheck.sh -p prod
```

Example 3: Check configurables with the 'demo' profile, doing a verbose comparison:

```
ccheck.sh -p demo -v
```

FUTURE ENHANCEMENTS:

Presently, this ccheck.sh v1.0.5 only reports configurables. It does not support changing configurables.

As the script is currently only capable of reporting, the '-y' option has no effect.

Some possible future enhancements are:

- * Extend reporting to suggesting configuration changes.

- * Provide an option to make changes to configurables that are safe to change immediately, and provide guidance on those configurables that are best set with guidance and planning.

- * Provide a way to specify custom exemptions for certain configurables.
- * Added multi-version support for backward compatibility. This version assumes P4D 2023.1+ (though will be useful for older versions).

9.6.4. edge_dump.sh

The `/p4/common/bin/edge_dump.sh` script is designed to create a seed checkpoint for an Edge server.

An edge server is naturally filtered, with certain database tables (e.g. db.have) excluded. In addition to implicit filtering, the server spec may specify additional tables to be excluded, e.g. by using the `ArchiveDataFilter` field of the server spec.

The script requires the SDP instance and the edge ServerID.

Usage

```
/p4/common/bin/edge_dump.sh <instance> <edge server id>
/p4/common/bin/edge_dump.sh 1 p4d_edge_syd
```

It will output the full path of the checkpoint to be copied to the edge server and used with [Section 9.6.26, “recover_edge.sh”](#)

9.6.5. edge_vars

The `/p4/common/bin/edge_vars` file is sourced by scripts that work on edge servers.

It sets the correct list db.* files that are edge-specific in the federated architecture. This version is dependent on the version of p4d in use; this script accounts for the P4D version.

It is not intended for users to call directly.

9.6.6. edge_shelf_replicate.sh

The `/p4/common/bin/edge_shelf_replicate.sh` script is intended to be run on an edge server and will ensure that all shelves are replicated to that edge server (by running `p4 print` on them).

Only use if directed to by Perforce Support or Perforce Consulting.

9.6.7. load_checkpoint.sh

The `/p4/common/bin/load_checkpoint.sh` script loads a checkpoint into `root` and `offline_db` for `commit/edge/replica` instance.

This script will replace your `/p4/<instance>/root` database files! **Be careful!**

If you want to create db files in `offline_db` then use [Section 9.4.11, “recreate_offline_db.sh”](#).

Usage

USAGE for load_checkpoint.sh v2.9.9:

```
load_checkpoint.sh {<checkpoint>|-latest} [<jnl.1> [<jnl.2> ...]] [-R|-F
<SafetyFactor>] [-i <instance>] [-s <ServerID>] [-t <Type>] [-verify {default|"Verify
Options"}] [-delay <delay>]] [-c] [-l] [-r] [-b] [-y] [-L <log>] [-si] [-d|-D]
```

or

```
load_checkpoint.sh [-h|-man]
```

DESCRIPTION:

This script loads a specified checkpoint into /p4/N/root and /p4/N/offline_db, where 'N' is the SDP instance name.

At the start of processing, preflight checks are done. Preflight checks include:

- * The specified checkpoint and corresponding *.md5 file must exist.
- * The specified checkpoint can be a file or a directory (for parallel checkpoint processing).
- * All journal files to replay (if any were specified) must exist.
- * The \$P4ROOT/server.id file must exist, unless '-s' is specified.
- * If the \$P4ROOT/server.id file exists and '-s' is specified, the values must match.
- * The \$P4ROOT/license file must exist, unless '-l' is specified or if the replica type does not require a license.
- * Basic SDP structure and key files must exist.

If the preflight passes, the p4d_N service is shutdown, and also the p4broker_N service is shutdown if configured.

If a P4LOG file exists, it is moved aside so there is a fresh p4d server log corresponding to operation after the checkpoint load.

If a P4JOURNAL file exists, it is moved aside as the old journal data is no longer relevant after a checkpoint replay. (Exception: If the P4JOURNAL is specified in a list of journals to reply, then it is not moved aside).

Next, any existing state* files in P4ROOT are removed.

Next, any existing database files in P4ROOT are preserved and moved aside, unless '-R' is specified to remove them.

Next, the specified checkpoint is loaded. Upon completion, the Helix Core server process, p4d_N, is started.

If the server to be started is a replica, the serviceUser configured for the replica is logged into the P4TARGET server. Any needed 'p4 trust' and 'p4 login' commands are done to enable replication.

Note that this part of the processing will fail if the correct super user password is not stored in the standard SDP password file,

```
/p4/common/config/.p4passwd.p4_N.admin
```

After starting the server, a local 'p4 trust' is done if needed, and then a 'p4login -service -v' and 'p4login -v'.

By default, the p4d_N service is started, but the p4broker_N service is not. Specify '-b' to restart both services.

Finally, the offline_db is rebuilt using the same specified checkpoint and journals.

ARGUMENTS AND OPTIONS:

<checkpoint>

Specify the path to the checkpoint file or directory to load. Exactly one checkpoint must be specified. If a checkpoint file is specified, a serial checkpoint replay will be done. If a checkpoint directory is specified, a parallel replay will be done using the individual files in the directory.

For checkpoint files:

The file may be a compressed or uncompressed checkpoint, and it may be a case sensitive or case-insensitive checkpoint. The checkpoint file must have a corresponding *.md5 checksum file in the same directory, with one of two name variations: If the checkpoint file is /somewhere/foo.gz, the checksum file may be named /somewhere/foo.gz.md5 or /somewhere/foo.md5.

For checkpoint directories:

This option is required unless the '-latest' option is used.

<jnl.1> [<jnl.2> ...]

Specify the path to the one or more journal files to replay after the checkpoint, in the correct sequence order.

-latest

Specify this as an alternative to providing a specific checkpoint file or directory. The script will then search for the latest *.md5 file in the \$CHECKPOINTS directory (), and use that to replay. The most recent *.md5 file determines which checkpoint to load, be it a file or directory.

-R Specify '-R' to remove db.* files in P4ROOT rather than moving them aside.

By default, databases are preserved for possible future for investigation. A folder named 'MovedDBs.<datestamp>' is created under the P4ROOT directory, and databases are moved there.

Keeping an extra copy of databases requires sufficient disk space to hold an extra copy of the db.* files.

If -R specified, old databases in P4ROOT are removed, along with state* and other files, and the server.locks directory.

-F <SafetyFactor>

When replacing an existing set of db.* files, a safety factor is used. This is simply the factor by which the size of pre-existing databases is multiplied when comparing against available disk space.

Specify '-F 0' to disable the safety factor check.

The disk space safety check is only meaningful if P4ROOT was previously populated with a full set of data.

Specifying a number greater than 1, say 1.2 (the default) gives more breathing room.

Specifying a value lower than 1, say 0.95, may be OK if you are certain the expanded-from-a-checkpoint db.* files are significantly smaller than size the prior set of db.* files.

This option is mutually exclusive with '-R'. If '-R' is used, databases are removed, and there is no need to calculate disk space.

-i <instance>

Specify the SDP instance. This can be omitted if SDP_INSTANCE is already defined.

-s <ServerID>

Specify the ServerID. This value is written into \$P4ROOT/server.id file.

If no \$P4ROOT/server.id file exists, this flag is required.

If the \$P4ROOT/server.id file exists, this argument is not needed. If this '-s <ServerID>' is given and a \$P4ROOT/server.id file exists, the value in the file must match the value specified with this argument.

-t <Type>

Specify the replica type tag if the checkpoint to be loaded is for an edge server or replica. The set of valid values for the replica type tag are defined in the documentation for mkrep.sh. See: mkrep.sh -man

If the type is specified, the '-s <ServerID>' is required.

If the SDP Server Spec Naming Standard is followed, the ServerID specified with '-s' will start with 'p4d_'. In that case, the value for '-t edge' value is inferred, and '-t' is not required.

If the type is specified or inferred, certain behaviors change based on the type:

- * If the type is edge, only the correct edge-specific subset of database tables are loaded.

- * The P4ROOT/license file check is suppressed unless the type is ha, ham, fs, for fsm (standby replicas usable with 'p4 failover').

Do not use this '-t <Type>' option if the checkpoint being loaded is for a master server.

For an edge server, an edge seed checkpoint created with edge_dump.sh must be used if the edge is filtered, e.g. if any of the *DataFilter fields in the server spec are used. If the edge server is not filtered by means other than being an edge server (for which certain tables are filtered by nature), a standard full checkpoint from the master can be used.

For a filtered forwarding replica, a proper seed checkpoint must be loaded. This can be created on the master using key options to p4d, including '-P <ServerID> -jd <SeedCkp>' on the master (possibly using the 'offline_db' to avoid downtime, similar to how edge_dump.sh works for edge servers).

WARNING: While this script is useful for seeding a new edge server, this script is NOT to be used for recovering or reseeding an existing edge server, because all edge-local database tables (mostly workspace data) would be lost. To recover an existing edge server, see the recover_edge.sh script.

Warning: If this option is specified with the incorrect type for the checkpoint specified, results will be unpredictable.

-verify default [-delay <delay>]

-verify "Verify Options" [-delay <delay>]

Specify '-verify' to initiate a call to 'p4verify.sh' after the server is online. On a replica, this can be useful to cause the server to pull missing archive files from its P4TARGET server. If this load_checkpoint.sh script is used in a recovery situation for a master server, this '-verify' option can be used to discover if archive files are missing after the metadata is recovered.

The 'p4verify.sh' script has a rich set of options. See 'p4verify.sh -man' for more info. The options to pass to p4verify.sh can be passed in a quoted list, or '-verify default' can be used to indicate these default options:

-o MISSING

By default, a fast verify is used if the p4d version is new enough (2021.1+). See 'p4verify.sh -man' for more information, specifically the description of the '-o MISSING' option.

In all cases, `p4verify.sh` is invoked as a background process; this `load_checkpoint.sh` script does not wait for it to complete. The `p4verify.sh` script will email as per normal when it completes.

The optional `delay` option specifies how long to wait until kicking off the `p4verify.sh` command, in seconds. The default is 600 seconds.

This is intended to give the replica time get caught up with metadata before the archive pulls are scheduled. The delay is a workaround for job079842.

`-c` Specify that SSL certificates are required, and not to be generated with `'p4d_N -Gc'`.

By default, if `'-c'` is not supplied and SSL certs are not available, certs are generated automatically with `'p4d_N -Gc'`.

`-l` Specify that the server is to start without a license file. By default, if there is no `$P4ROOT/license` file, this script will abort. Note that if `'-l'` is specified and a license file is actually needed, the attempt this script makes to start the server after loading the checkpoint will fail.

If `'-t <type>'` is specified, the license check is skipped unless the type is `'ha'`, `'ham'`, `'fs,'` or `'fsm'`. Replicas that are potential targets for a `'p4 failover'` need a license file for a failover to work.

`-r` Specify `'-r'` to replay only to P4ROOT. By default, this script replays both to P4ROOT and the `offline_db`.

`-b` Specify `'-b'` to start the a `p4broker` process (if configured). By default the `p4d` process is started after loading the checkpoint, but the `p4broker` process is not. This can be useful to ensure the human administrator has an opportunity to do sanity checks before enabling the broker to allow access by end users (if the broker is deployed for this usage).

`-y` Use the `'-y'` flag to bypass an interactive warning and confirmation prompt.

`-L <log>`

Specify the path to a log file. By default, all output (stdout and stderr) goes to:

```
/p4/<instance>/logs/load_checkpoint.<timestamp>.log
```

NOTE: This script is self-logging. That is, output displayed on the screen is simultaneously captured in the log file. Do not run this script with redirection operators like `'> log'` or `'2>&1'`, and do not use `'tee.'`

`-si` Operate silently. All output (stdout and stderr) is redirected to the log only; no output appears on the terminal.

`-d` Set debugging verbosity.

`-D` Extreme debugging verbosity using bash 'set -x' mode.

HELP OPTIONS:

`-h` Display short help message
`-man` Display man-style help message

USAGE TIP:

All the non-interactive examples below illustrate the practice of using redirects to create an extra log file named 'load.log' in the \$LOGS directory for the instance. This load.log file is identical to, and in addition to, the standard timestamped log generated by this script. The intent of this practice is to leave a trail of when a checkpoint was last loaded on any given server machine.

EXAMPLES:

EXAMPLE 1: Non-interactive Usage

Non-interactive usage (bash syntax) to load a checkpoint:

```
nohup /load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.4025.gz -i 1 -y < /dev/null > /p4/1/logs/load.log 2>&1 &
```

Then, monitor with:

```
tail -f $(ls -t $LOGS/load_checkpoint.*.log|head -1)
```

EXAMPLE 2: Checkpoint Load then Verify, for the SDP Instance alpha.

Non-interactive usage (bash syntax) to load a checkpoint followed by a full verify of recent archives files only with other options passed to verify.sh:

```
nohup /load_checkpoint.sh /p4/alpha/checkpoints/p4_alpha.ckp.95442.gz -i alpha -verify -recent -nu -ns -y < /dev/null > /p4/alpha/logs/load.log 2>&1 &
```

EXAMPLE 3: Load Checkpoint and Journals

Non-interactive usage (bash syntax) to loading a checkpoint and subsequent journals:

```
nohup /load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.4025.gz /p4/1/checkpoints/p4_1.jnl.4025 /p4/1/checkpoints/p4_1.jnl.4026 -i 1 -y < /dev/null > /p4/1/logs/load.log 2>&1 &
```

Then, monitor with:

```
tail -f $(ls -t $LOGS/load_checkpoint.*.log|head -1)
```

EXAMPLE 4: Interactive usage.

Interactive usage to load a checkpoint with no license file.

```
/load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.4025.gz -i 1 -l
```

With interactive usage, logging still occurs; all output to the screen is captured.

Note that non-interactive usage with `nohup` is recommended for checkpoints with a long replay duration, to make operation more reliable in event of a shell session disconnect. Alternately, running interactively in a 'screen' session (if 'screen' is available) provides similar protection against shell session disconnects.

EXAMPLE 5: Seed New Edge

Seeding a new edge server.

```
nohup /load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.4025.gz -i 1 -s p4d_edge_syd < /dev/null > /p4/1/logs/load.log 2>&1 &
```

WARNING: While this script is useful for seeding a new edge server, this script is NOT to be used for recovering or reseeding an existing edge server, because all edge-local database tables (mostly workspace data) would be lost. To recover an existing edge server, see the `recover_edge.sh` script.

EXAMPLE 6: Seed New Edge and Verify

Seeding a new edge server and then do a verify with default options.

```
nohup /load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.4025.gz -i 1 -s p4d_edge_syd -verify default < /dev/null > /p4/1/logs/load.log 2>&1 &
```

EXAMPLE 7: Load a Parallel Checkpoint on an Edge and Verify Recent

This non-interactive example loads a parallel checkpoint directory. The usage difference is that the checkpoint path provided is a parallel checkpoint directory rather than a single checkpoint file. This example loads the checkpoint for a new edge server, and verifies only the most recent 3 changes in each depot. The delay before calling `p4verify.sh`, 10 minutes (600) by default, is shortened to 5 seconds in this example.

```
nohup /load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.4025 -i 1 -s p4d_edge_syd -verify "-o MISSING -recent=3 -ns -L /p4/1/logs/p4verify.fast_and_recent.log" -delay 5 -y < /dev/null > /p4/1/logs/load.log 2>&1 &
```

9.6.8. gen_default_broker_cfg.sh

The `/p4/common/bin/gen_default_broker_cfg.sh` script generates an SDP instance-specific variant of the generic P4Broker config file. Display to standard output.

Usage:

```
cd /p4/common/bin
gen_default_broker_cfg.sh 1 > /tmp/p4broker.cfg.ToBeReviewed
```

The final p4broker.cfg should end up here:

```
/p4/common/config/p4_${SDP_INSTANCE}.${SERVERID}.broker.cfg
```

9.6.9. journal_watch.sh

The `/p4/common/bin/journal_watch.sh` script will check disk space available to P4JOURNAL and trigger a journal rotation based on specified thresholds. This is useful in case you are in danger of running out of disk space and your rotated journal files are stored on a separate partition than the active journal.

This script is using the following external variables:

- `SDP_INSTANCE` - The instance of Perforce that is being backed up. If not set in environment, pass in as argument to script.
- `P4JOURNALWARN` - Amount of space left (K,M,G,%) before min journal space where an email alert is sent
- `P4JOURNALWARNALERT` - Send an alert if warn threshold is reached (true/false, default: false)
- `P4JOURNALROTATE` - Amount of space left (K,M,G,%) before min journal space to trigger a journal rotation
- `P4OVERRIDEKEEPJNL` - Allow script to temporarily override `KEEPJNL` to retain enough journals to replay against oldest checkpoint (true/false, default: false)

Usage

```
/p4/common/bin/journal_watch.sh <P4JOURNALWARN> <P4JOURNALWARNALERT> <P4JOURNALROTATE>
<P4OVERRIDEKEEPJNL (Optional)>
```

Examples

Run from CLI that will warn via email if less than 20% is available and rotate journal when less than 10% is available

```
./journal_watch.sh 20% TRUE 10% TRUE
```

Cron job that will warn via email if less than 20% is available and rotate journal when less than 10% is available

```
30 * * * * [ -e /p4/common/bin ] && /p4/common/bin/run_if_master.sh ${INSTANCE}
/p4/common/bin/journal_watch.sh ${INSTANCE} 20\% TRUE 10\% TRUE
```

9.6.10. kill_idle.sh

The `/p4/common/bin/kill_idle.sh` script runs `p4 monitor terminate` on all processes showing in the output of `p4 monitor show` that are in the IDLE state.

Usage

```
/p4/common/bin/kill_idle.sh <instance>
/p4/common/bin/kill_idle.sh 1
```

9.6.11. mkdirs.sh

The `mkdirs.sh` script is intended for the setup and configuration of a **new** Helix Core instance. It should be run only for adding a new instance, not against an existing instance.

Usage

USAGE for mkdirs.sh v4.10.0:

```
mkdirs.sh <instance> [-s <ServerID>] [-t <ServerType>] [-tp <TargetPort>] [-lp
<ListenPort>] [-I <svc>[,<svc2>]] [-MDD /bigdisk] [-MLG /jn1] [-MDB1 /db1] [-MDB2
/db2] [-f] [-p] [-test [-clean]] [-n] [-L <log>] [-d|-D]
```

or

```
mkdirs.sh [-h|-man]
```

DESCRIPTION:

== Overview ==

This script initializes an SDP instance on a single machine.

This script is intended to support two scenarios:

- * First time SDP installation on a given machine.
- * Adding new SDP instances (separate Helix Core data sets) to an existing SDP installation on a given machine.

And SDP instance is a single Helix Core data set, with its own unique set of one set of users, changelist numbers, jobs, labels, versioned files, etc. An organization may run a single instance or multiple instances.

This is intended to be run either as root or as the operating system user account (OSUSER) that p4d is configured to run as, typically 'perforce'. It should be run as root for the initial install. Subsequent additions of new instances do not require root.

== Directory Structure ==

If an initial install as done by a user other than root, various directories must exist and be writable and owned by 'perforce' before starting:

- * /p4
- * /hxdepots
- * /hxlogs
- * /hxmetadata

The directories starting with '/hx' are configurable.

This script creates an init script in the /p4/N/bin directory.

== Crontab ==

Crontabs are generated for all server types except p4broker.

After running this script, set up the crontab based on templates generated as /p4/common/etc/cron.d. For convenience, a sample crontab is generated for the current machine as /p4/p4.crontab.<SDPInstance> (or /p4/p4.crontab.<SDPInstance>.new if the former name exists).

These files should be copied or merged into any existing files named with this convention:

```
/p4/common/etc/cron.d/crontab.<osuser>.<host>
```

where <osuser> is the user that services run as (typically 'perforce'), and <host> is the short hostname (as returned by a 'hostname -s' command).

REQUIRED PARAMETERS:

<instance>

Specify the SDP instance name to add. This is a reference to the Perforce Helix Core data set.

OPTIONS:

-s <ServerID>

Specify the ServerID, overriding the REPLICA_ID setting in the configuration file.

-S <TargetServerID>

Specify the ServerID of the P4TARGET of the server being installed. Use this only when setting up an HA replica of an edge server.

-t <ServerType>

Specify the server type, overriding the SERVER_TYPE setting in the config file. Valid values are:

- * p4d_master - A master/commit server.
- * p4d_replica - A replica with all metadata from the master (not filtered in any way).

- * p4d_filtered_replica - A filtered replica or filtered forwarding replica.
- * p4d_edge - An edge server.
- * p4d_edge_replica - Replica of an edge server. If used, '-S <TargetServerID>' is required.
- * p4broker - An SDP host running only a standalone p4broker, with no p4d.
- * p4proxy - An SDP host running only a standalone p4p with no p4d.

-tp <TargetPort>

Specify the target port. Use only if ServerType is p4proxy and p4broker.

-lp <ListenPort>

Specify the listen port. Use only if ServerType is p4proxy and p4broker.

-I [<svc>[,<svc2>]]

Specify additional init scripts to be added to /p4/<instance>/bin for the instance.

By default, the p4p service is installed only if '-t p4proxy' is specified, and p4dtg is never installed by default. Valid values to specify are 'p4p' and 'dtg' (for the P4DTG init script).

If services are not installed by default, they can be added later using templates in /p4/common/etc/init.d. Also, templates for systemd service files are supplied in /p4/common/etc/systemd/system.

-MDD /bigdisk

-MLG /jnl

-MDB1 /db1

-MDB2 /db2

Specify the '-M*' to specify mount points, overriding DD/LG/DB1/DB2 settings in the config file. Sample:

```
-MDD /bigdisk -MLG /jnl -MDB1 /fast
```

If -MDB2 is not specified, it is set the the same value as -MDB1 if that is set, or else it defaults to the same default value as DB1.

-f Specify -f 'fast mode' to skip chown/chmod commands on depot files.

This should only be used when you are certain the ownership and permissions are correct, and if you have large amounts of existing data for which the chown/chmod of the directory tree would be slow.

-p Specify '-p' to halt processing after preflight checks are complete, and before actual processing starts. By default, processing starts immediately upon successful completion of preflight checks.

-L <log>

Specify the path to a log file, or the special value 'off' to disable logging. By default, all output (stdout and stderr) goes to this file

in the current directory:

```
mkdirs.<instance>.<timestamp>.log
```

NOTE: This script is self-logging. That is, output displayed on the screen is simultaneously captured in the log file. Do not run this script with redirection operators like '> log' or '>&1', and do not use 'tee'.

DEBUGGING OPTIONS:

-test

Specify '-test' to execute a simulated install to /tmp/p4 as the install root (rather than /p4), and with the mount point directories specified in the configuration file prefixed with /tmp/hxmounts, defaulting to:

```
* /tmp/hxmounts/hxdepots
* /tmp/hxmounts/hxlogs
* /tmp/hxmounts/hxmetadata
```

-clean

Specify '-clean' with '-test' to clean up from prior test installs, which will result in removal of files/folders installed under /tmp/hxmounts and /tmp/p4.

Do not specify '-clean' if you want to test a series of installs.

-n No-Op. In No-Op mode, no actions that affect data or structures are taken. Instead, commands that would be run are displayed. This is an alternative to -test. Unlike '-p' which stops after the preflight checks, with '-n' more processing logic can be exercised, with greater detail about what commands that would be executed without '-n'.

-d Increase verbosity for debugging.

-D Set extreme debugging verbosity, using bash '-x' mode. Also implies -d.

HELP OPTIONS:

```
-h Display short help message
-man Display man-style help message
```

FILES:

The mkdirs.sh script uses a configuration file for many settings. A sample file, mkdirs.cfg, is included with the SDP. After determining your SDP instance name (e.g. '1' or 'abc'), create a configuration file for it named mkdirs.<N>.cfg, replacing 'N' with your instance.

Running 'mkdirs.sh N' will load configuration settings from mkdirs.N.cfg.

UPGRADING SDP:

This script can be useful in testing and upgrading to new versions of the SDP, when the '-test' flag is used.

EXAMPLES:

Example 1: Setup of first instance

Setup of the first instance on a machine using the default instance name, '1', executed after using sudo to become root:

```
$ sudo su -
$ cd /hxdepots/sdp/Server/Unix/setup
$ vi makedirs.cfg
```

Adjust settings as desired, e.g P4PORT, P4BROKERPORT, etc.

```
$ ./makedirs.sh 1
```

A log will be generated, makedirs.1.<timestamp>.log

Example 2: Setup of additional instance named 'abc'.

Setup a second instance on the machine, which will be a separate Helix Core instance with its own P4ROOT, its own set of users and changelists, and its own license file (copied from the master instance).

Note that while the first run of makedirs.sh on a given machine should be done as root, but subsequent instance additions should be done as the 'perforce' user (or whatever operating system user accounts Perforce Helix services run as).

```
$ sudo su - perforce
$ cd /hxdepots/sdp/Server/Unix/setup
$ cp -p makedirs.cfg makedirs.abc.cfg
$ vi makedirs.abc.cfg
```

Adjust settings in makedirs.abc.cfg as desired, e.g P4PORT, P4BROKERPORT, etc.

```
$ ./makedirs.sh abc
```

A log will be generated, makedirs.abc.<timestamp>.log

Example 3: Setup of additional instance named 'alpha' to run a standalone p4p:

```
$ ./makedirs.sh alpha -t p4proxy
```

Example 4: Setup of a stand instance named '1' to run a standalone p4broker:

```
$ ./makedirs.sh 1 -t p4broker
```

9.6.12. p4d_base

The `/p4/common/bin/p4d_base` script is the script to start/stop/restart the `p4d` instance.

It is called by `p4d_<instance>_init` script (and thus also `systemctl` on systemd Linux distributions). It

is not intended to be called by users directly.

9.6.13. p4broker_base

The `/p4/common/bin/p4broker_base` script is very similar to [Section 9.6.12, “p4d_base”](#) but for the `p4broker` service instance.

See [p4broker in SysAdmin Guide](#)

9.6.14. p4ftpd_base

The `/p4/common/bin/p4ftpd_base` script is very similar to [Section 9.6.12, “p4d_base”](#) but for the `p4ftp` service instance. The `p4ftp` has been deprecated; this may be removed in a future SDP release.

This product is very seldom used these days!

See [P4FTP Installation Guide](#).

9.6.15. p4p_base

The `/p4/common/bin/p4p_base` is very similar to [Section 9.6.12, “p4d_base”](#) but for the `p4p` (P4 Proxy) service instance.

See [p4proxy in SysAdmin Guide](#)

9.6.16. p4pcm.pl

The `/p4/common/bin/p4pcm.pl` script is a utility to remove files in the proxy cache if the amount of free disk space falls below the low threshold.

Usage

9.6.17. p4review.py

The `/p4/common/bin/p4review.py` script sends out email containing the change descriptions to users who are configured as reviewers for affected files (done by setting the `Reviews:` field in the user specification). This script is a version of the `p4review.py` script that is available on the Perforce Web site, but has been modified to use the server instance number. It relies on a configuration file in `/p4/common/config`, called `p4_<instance>.p4review.cfg`.

This is not required if you have installed Swarm which also performs notification functions and is easier for users to configure.

Usage

```
/p4/common/bin/p4review.py # Uses config file as above
```

9.6.18. p4review2.py

The `/p4/common/bin/p4review2.py` script is an enhanced version of [Section 9.6.17, “p4review.py”](#)

1. Run `p4review2.py --sample-config > p4review.conf`
2. Edit the file `p4review.conf`
3. Add a crontab similar to this:
 - `**** python2.7 /path/to/p4review2.py -c /path/to/p4review.conf`

Features:

- Prevent multiple copies running concurrently with a simple lock file.
- Logging support built-in.
- Takes command-line options.
- Configurable subject and email templates.
- Use P4Python when available and use P4 (the CLI) as a fallback.
- Option to send a *single* email per user per invocation instead of multiple ones.
- Reads config from a INI-like file using ConfigParser
- Have command line options that overrides environment variables.
- Handles unicode-enabled server **and** non-ASCII characters on a non-unicode-enabled server.
- Option to opt-in (`--opt-in-path`) reviews globally (for migration from old review daemon).
- Configurable URLs for changes/jobs/users (for swarm).
- Able to limit the maximum email message size with a configurable.
- SMTP auth and TLS (not SSL) support.
- Handles P4AUTH (optional; use of P4AUTH is no longer recommended).

9.6.19. proxy_rotate.sh

The `/p4/common/bin/proxy_rotate.sh` rotates the proxy log file. It is intended for use on a server machine that has only proxy running. When a proxy is run on a p4d server machine, the `daily_checkpoint.sh` script takes care of rotating the proxy log.

It can be added to a crontab for e.g. daily log rotation.

Usage

```
/p4/common/bin/proxy_rotate.sh <instance>
/p4/common/bin/proxy_rotate.sh 1
```

9.6.20. p4sanity_check.sh

The `/p4/common/bin/p4sanity_check.sh` script is a simple script to run:

- p4 set
- p4 info
- p4 changes -m 10

Usage

```
/p4/common/bin/p4sanity_check.sh <instance>
/p4/common/bin/p4sanity_check.sh 1
```

9.6.21. p4dstate.sh

The `/p4/common/bin/p4dstate.sh` is a trouble-shooting script for use when directed by support, e.g. in situations such as server hanging, major locking problems etc.

It is an "SDP-aware" version of the [standard p4dstate.sh](#) so that it only requires the SDP instance to be specified as a parameter (since the location of logs etc are defined by SDP).

Usage

```
sudo /p4/common/bin/p4dstate.sh <instance>
sudo /p4/common/bin/p4dstate.sh 1
```

9.6.22. ps_functions.sh

The `/p4/common/bin/ps_functions.sh` library file contains common functions for using 'ps' to check on process ids. It is not intended to be called by users.

```
get_pids ($exe)
```

Usage

```
Call with an exe name, e.g. /p4/1/bin/p4web_1
```

Examples

```
p4web_pids=$(get_pids $P4WEBBIN)
p4broker_pids=$(get_pids $P4BROKERBIN)
```

9.6.23. pull.sh

The `/p4/common/bin/pull.sh` is a reference pull trigger implementation for [External Archive Transfer using pull-archive and edge-content triggers](#)

It is a fast content transfer mechanism using Aspera (and can be adapted to other similar UDP based products.) An Edge server uses this trigger to pull files from its upstream Commit server. It replaces or augments the built in replication archive pull and is useful in scenarios where there are

lots of large (binary) files and commit/edge are geographically distributed with high latency and/or low bandwidth between them.

See also companion trigger [Section 9.6.31](#), “`submit.sh`”.

It is based around getting a list of files to copy from commit to edge, then doing the file transfer using `ascp` (Aspera file copy).

The configurable `pull.trigger.dir` should be set to a temp folder like `/p4/1/tmp`.

Startup commands look like:

```
startup.2=pull -i 1 -u --trigger --batch=1000
```

The trigger entry for the pull commands looks like this:

```
pull_archive pull-archive pull "/p4/common/bin/triggers/pull.sh %archiveList%"
```

There are some pull trigger options, but they are not necessary with Aspera. Aspera works best if you give it the max batch size of 1000 and set up 1 or more threads. Note, that each thread will use the max bandwidth you specify, so a single pull-trigger thread is probably all you will want.

The `ascp` user needs to have ssl public keys set up or export `ASPERA_SCP_PASS`.

The `ascp` user should be set up with the target as / with full write access to the volume where the depot files are located. The easiest way to do that is to use the same user that is running the p4d service.

ensure `ascp` is correctly configured and working in your environment: <https://www-01.ibm.com/support/docview.wss?uid=ibm10747281> (search for "ascp connectivity testing")

Standard SDP environment is assumed, e.g P4USER, P4PORT, OSUSER, P4BIN, etc. are set, PATH is appropriate, and a super user is logged in with a non-expiring ticket.

Read the trigger comments for any customization requirements required for your environment.

See also the test version of the script: [Section 9.6.24](#), “`pull_test.sh`”

See the `/p4/common/bin/triggers/pull.sh` script for details and to customize for your environment.

9.6.24. `pull_test.sh`

The `/p4/common/bin/pull_test.sh` script is a test script.

THIS IS A TEST SCRIPT - it substitutes for [Section 9.6.23](#), “`pull.sh`” which uses Aspera’s `ascp` and replaces that with Linux standard `scp` utility. **IT IS NOT**

INTENDED FOR PRODUCTION USE!!!!

If you don't have an Aspera license, then you can test with this script to understand the process.

See the `/p4/common/bin/triggers/pull_test.sh` script for details.

There is a demonstrator project showing usage: <https://github.com/rcowham/p4d-edge-pull-demo>

9.6.25. `purge_revisions.sh`

The `/p4/common/bin/purge_revisions.sh` script will allow you to archive files and optionally purge files based on a configurable number of days and minimum revisions that you want to keep. This is useful if you want to keep a certain number of days worth of files instead of a specific number of revisions.

Note: If you run this script with purge mode disabled, and then enable it after the fact, all previously archived files specified in the configuration file will be purged if the configured criteria is met.

Prior to running this script, you may want to disable server locks for archive to reduce impact to end users.

See: <https://www.perforce.com/perforce/doc.current/manuals/cmdref/Content/CmdRef/configurables.configurables.html#server.locks.archive>

Parameters:

- `SDP_INSTANCE` - The instance of Perforce that is being backed up. If not set in environment, pass in as argument to script.
- `P4_ARCHIVE_CONFIG` - The location of the config file used to determine retention. If not set in environment, pass in as argument to script. This can be stored on a physical disk or somewhere in perforce.
- `P4_ARCHIVE_DEPOT` - Depot to archive the files in (string)
- `P4_ARCHIVE_REPORT_MODE` - Do not archive revisions; report on which revisions would have been archived (bool - default: true)
- `P4_ARCHIVE_TEXT` - Archive text files (or other revisions stored in delta format, such as files of type binary+D) (bool - default: false)
- `P4_PURGE_MODE` - Enables purging of files after they are archived (bool - default: false)

Config File Format

The config file should contain a list of file paths, number of days and minimum of revisions to keep in a tab delimited format.

```
<PATH> <DAYS> <MINIMUM REVISIONS>
```

Example:

```
//test/1.txt    10  1
//test/2.txt    1   3
//test/3.txt    10 10
//test/4.txt    30  3
//test/5.txt    30  8
```

Usage

```
/p4/common/bin/purge_revisions.sh <SDP_INSTANCE> <P4_ARCHIVE_CONFIG>
<P4_ARCHIVE_DEPOT> <P4_ARCHIVE_REPORT_MODE (Optional)> 4_ARCHIVE_TEXT (Optional)>
<P4_PURGE_MODE (Optional)>
```

Examples

Run from CLI that will archive files as defined in the config file

```
./purge_revisions.sh 1 /p4/common/config/p4_1.p4purge.cfg archive FALSE
```

Cron job that will will archive files as defined in the config file, including text files

```
30 0 * * * [ -e /p4/common/bin ] && /p4/common/bin/run_if_master.sh ${INSTANCE}
/p4/common/bin/purge_revisions.sh $INSTANCE /p4/common/config/p4_1.p4purge.cfg
archive FALSE FALSE
```

9.6.26. recover_edge.sh

The `/p4/common/bin/recover_edge.sh` script is designed to rebuild an Edge server from a seed checkpoint from the master while keeping the existing edge specific data.

You have to first copy the seed checkpoint from the master, created with [Section 9.6.4, “edge_dump.sh”](#), to the edge server before running this script. (Alternately, a full checkpoint from the master can be used so long as the edge server spec does not specify any filtering, e.g. does not use `ArchiveDataFilter`.)

Then run this script on the Edge server host with the instance number and full path of the master seed checkpoint as parameters.

Usage

```
/p4/common/bin/recover_edge.sh <instance> <absolute path to checkpoint>
/p4/common/bin/recover_edge.sh 1 /p4/1/checkpoints/p4_1.edge_syd.seed.ckp.9188.gz
```

9.6.27. replica_cleanup.sh

The `/p4/common/bin/replica_cleanup.sh` script performs the following actions for a replica:

- rotate logs
- remove old checkpoints and journals
- remove old logs

This should be used on replicas for which the `sync_replica.sh` is not used.

Usage

```
/p4/common/bin/replica_cleanup.sh <instance>
/p4/common/bin/replica_cleanup.sh 1
```

9.6.28. replica_status.sh

The `/p4/common/bin/replica_status.sh` script is regularly run by crontab on a replica or edge (using [Section 9.4.15, “run_if_replica.sh”](#)).

```
0 8 * * * [ -e /p4/common/bin ] && /p4/common/bin/run_if_replica.sh ${INSTANCE}
/p4/common/bin/replica_status.sh ${INSTANCE} > /dev/null
0 8 * * * [ -e /p4/common/bin ] && /p4/common/bin/run_if_edge.sh ${INSTANCE}
/p4/common/bin/replica_status.sh ${INSTANCE} > /dev/null
```

It performs a `p4 pull -lj` command on the replica to report current replication status, and emails this to the standard SDP administrator email on a daily basis. This is useful for monitoring purposes to detect replica lag or similar problems.

If you are using enhanced monitoring such as [p4prometheus](#) then this script may not be required.

Usage

```
/p4/common/bin/replica_status.sh <instance>
/p4/common/bin/replica_status.sh 1
```

9.6.29. request_replica_checkpoint.sh

The `/p4/common/bin/request_replica_checkpoint.sh` script is intended to be run on a standby replica. It essentially just calls `'p4 admin checkpoint -Z'` to request a checkpoint and exits. The actual checkpoint is created on the next journal rotation on the master.

Usage

```
/p4/common/bin/request_replica_checkpoint.sh <instance>
/p4/common/bin/request_replica_checkpoint.sh 1
```

9.6.30. rotate_journal.sh

The `/p4/common/bin/rotate_journal.sh` script is a convenience script to perform the following

actions for the specified instance (single parameter):

- rotate live journal
- replay it to the `offline_db`
- rotate logs files according to the settings in `p4_vars` for things like `KEEP_LOGS`

It has several use cases:

- For sites with large, long-running checkpoints, it can be used to schedule journal rotations to occur more frequently than `daily_checkpoint.sh` is run.
- It can be used to trigger checkpoints to run on edge servers.

Usage

```
/p4/common/bin/rotate_journal.sh <instance>
/p4/common/bin/rotate_journal.sh 1
```

9.6.31. submit.sh

The `/p4/common/bin/submit.sh` script is an example submit trigger for [External Archive Transfer using pull-archive and edge-content triggers](#)

This is a reference edge-content trigger for use with an Edge/Commit server topology - the Edge server uses this trigger to transmit files which are being submitted to the Commit instead of using its normal file transfer mechanism. This trigger uses Aspera for fast file transfer, and UDP, rather than TCP and is typically much faster, especially with high latency connections.

Companion trigger/script to [Section 9.6.23, “pull.sh”](#)

Uses `fstat -Ob` with some filtering to generate a list of files to be copied. Create a temp file with the filename pairs expected by ascp, and then perform the copy.

This configurable must be set:

```
rpl.submit.nocopy=1
```

The edge-content trigger looks like this:

```
EdgeSubmit edge-content //... "/p4/common/bin/triggers/ascpSubmit.sh %changelist%"
```

The `ascp` user needs to have `ssl` public keys set up or export `ASPERA_SCP_PASS`. The `ascp` user should be set up with the target as `/` with full write access to the volume where the depot files are located. The easiest way to do that is to use the same user that is running the `p4d` service.

ensure `ascp` is correctly configured and working in your environment: <https://www-01.ibm.com/support/docview.wss?uid=ibm10747281> (search for "ascp")

connectivity testing")

Standard SDP environment is assumed, e.g P4USER, P4PORT, OSUSER, P4BIN, etc. are set, PATH is appropriate, and a super user is logged in with a non-expiring ticket.

See the test version of this script below: [Section 9.6.32, “submit_test.sh”](#)

See the `/p4/common/bin/triggers/submit.sh` script for details and to customize for your environment.

9.6.32. submit_test.sh

The `/p4/common/bin/submit_test.sh` script is a test script.

THIS IS A TEST SCRIPT - it substitutes for [Section 9.6.31, “submit.sh”](#) (which uses Aspera) - and replaces `ascp` with Linux standard `scp`. IT IS NOT INTENDED FOR PRODUCTION USE!!!!

If you don't have an Aspera license, then you can test with this script to understand the process.

See the `/p4/common/bin/triggers/submit_test.sh` for details.

There is a demonstrator project showing usage: <https://github.com/rcowham/p4d-edge-pull-demo>

9.6.33. sync_replica.sh

The `/p4/common/bin/sync_replica.sh` script is included in the standard crontab for a replica.

It runs `rsync` to mirror the `/p4/1/checkpoints` (assuming instance `1`) directory to the replica machine.

It then uses the latest checkpoint in that directory to update the local `offline_db` directory for the replica.

This ensures that the replica can be quickly and easily reseeded if required without having to first copy checkpoints locally (which can take hours over slow WAN links).

Usage

```
/p4/common/bin/sync_replica.sh <instance>
/p4/common/bin/sync_replica.sh 1
```

9.6.34. templates directory

This sub-directory of `/p4/common/bin` contains some files which can be used as templates for new commands if you wish:

- `template.pl` - Perl
- `template.py` - Python
- `template.py.cfg` - config file for python

- `template.sh` - Bash

They are not intended to be run directly.

9.6.35. `update_limits.py`

The `/p4/common/bin/update_limits.py` script is a Python script which is intended to be called from a crontab entry one per hour. It must be wrapped with the `p4master_run` script.

It ensures that all current users are added to the `limits` group. This makes it easy for an administrator to configure global limits on values such as `MaxScanRows`, `MaxSearchResults` etc. This can reduce load on a heavily loaded instance.

For more information:

- [Maximizing Perforce Helix Core Performance](#)
- [Multiple MaxScanRows and similar values](#)

Usage

```
/p4/common/bin/update_limits.py <instance>  
/p4/common/bin/update_limits.py 1
```

Chapter 10. Sample Procedures

This section describes sample procedures using the SDP tools described above, given certain scenarios.

10.1. Installing Python3 and P4Python

Python3 and P4Python are useful for custom automation, including triggers.

Installing Python3 and P4Python is best done using packages. First, set up the machine to download packages from Perforce Software, following the guidance appropriate for your platform on the [Perforce Packages](#) page.

Then install Python3 and P4Python Packages with the command appropriate for your operating system. For RHEL/Rocky Linux family, use:

```
sudo yum install perforce-p4python3
```

For the Debian/Ubuntu family, use:

```
sudo apt update
sudo apt install perforce-p4python3
```

It is possible to have multiple versions of Python installed, possibly Python 2.7 (the end of the Python 2 line) and various Python 3.x versions, and possibly multiple versions either or both of Python 2 and Python 3. Whether having multiple versions is desirable or necessary depends on what software on the machine uses Python; that discussion is outside the scope of this document. However, being aware of this possibility is important for installing in various existing environments.

The behaviors of the `perforce-python3` package install vary slightly depending on what is already installed, and are optimized to avoid disrupting existing software.

- If no prior version of Python 3 exists on the machine when the `perforce-p4python3` package is installed, then the newly installed Python 3 will be established as the default, such that calling `python3` (a symlink) will implicitly refer to the just-installed Python 3 version. **The P4Python module will be available by calling `python3`.**
- If Python 3.8 exists on the machine when the `perforce-p4python3` package is installed, P4Python will be added to the existing Python 3.8 install. **The P4Python module will be available by calling `python3`.**
- If there is already some other version of Python 3.x installed but not 3.8, such as Python 3.6, installing the `perforce-p4python3` package will add a new Python 3.8 installation with the version of Python 3 it uses (e.g. `python3.8`), but it will **not** adjust the existing `python3` symlink. **The P4Python module will not be available with `python3`.** You can at that point decide to manually adjust the `python3` symlink to point to `python3.8`, though this has some risk of breaking other things (such as custom triggers) that require the other version of Python3

if it was actively used. Alternately, you can adjust the shebang lines of specific scripts that use P4Python to refer to `python3.8` specifically rather than just `python3`. In any case, avoid using `python2` or just `python`, both of which by convention refer to Python 2.

10.2. Installing CheckCaseTrigger.py

This trigger is very useful to avoid people accidentally checking in files on a case-sensitive server which only differ in case from an existing file (or directory).

This trigger requires `python3`, and must also have P4Python installed. See: [Section 10.1, “Installing Python3 and P4Python”](#).

The trigger to install is part of the SDP but by default is in `/p4/sdp/Unsupported/Samples/triggers`.

To install:

1. Install p4python. See: [Section 10.1, “Installing Python3 and P4Python”](#).
2. Copy the trigger and dependencies to appropriate directory

```
mkdir -p /p4/common/site/bin/triggers
cp /p4/sdp/Unsupported/Samples/triggers/CheckCaseTrigger.py
/p4/common/site/bin/triggers/
cp /p4/sdp/Unsupported/Samples/triggers/P4Trigger.py /p4/common/site/bin/triggers/
```

3. Edit the `shebang` line (first line) at the start of the trigger if necessary, e.g. change to:

```
#!/bin/env python3
```

Usually `python3` is appropriate.

1. Test on an existing (small) changelist:

```
p4 changes -s submitted -m 9
```

pick a suitable changelist number, e.g. 1234

```
/p4/common/site/bin/triggers/CheckCaseTrigger.py 1234
```

2. Test that it works
 - a. Add appropriate line to triggers table:

```
CheckCaseTrigger submit-change //test/...
"/p4/common/site/bin/triggers/CheckCaseTrigger.py %changelist%"
```

- b. Create test workspace
 - c. Submit simple `Test.txt`
 - d. Attempt to submit `test.txt` and check for error
3. Change triggers table to valid version/path:

```
CheckCaseTrigger submit-change //...
"/p4/common/site/bin/triggers/CheckCaseTrigger.py %changelist%"
```

10.3. Swarm JIRA Link

Here is an example of linking to cloud JIRA in `config.php`:

```
'jira' => array(
    'host' => 'https://example.atlassian.net/',
    'user' => 'p4jira@example.com',
    'password' => '<API-Token>',
    'link_to_jobs' => 'true',
),
```

No need to get complicated with `.pem` files or `'http_client_options'` section. Just specify `https://` prefix as above.

Login to user account on Atlassian URL as above, and then create an API token by going to this URL:

<https://id.atlassian.com/manage-profile/security/api-tokens>

This curl request tested the API:

```
curl https://example.atlassian.net/rest/api/latest/project --user
p4jira@example.com:<API-TOKEN>
```

The above should list all active projects:

Example JSON response

```
{"expand": "description,lead,issueTypes,url,projectKeys,permissions,insight", "self": "https://example.atlassian.net/rest/api/2/project/11904", "id": "11904", "key": "ULG", "name": "Ultimate Game"}
```

Check that the provided JIRA account has access to all required projects to be linked (and that it isn't missing some)! See below.

Example list of projects accessible to JIRA account

```
$ curl --user 'p4jira@example.com:<API-TOKEN>'
https://example.atlassian.net/rest/api/latest/project | jq > projects.txt

$ egrep "name|key" projects.txt
egrep "name|key" projects.txt
  "key": "PRJA",
  "name": "Project A",
  "key": "PRJB",
  "name": "Project B",
```

10.4. Reseeding an Edge Server

Perforce Helix Edge Servers are a form of replica that replicates "persistent history" data such as submitted changelists from the master server, while maintaining local databases for "work-in-progress" data, to include user workspaces, lists of files checked out in user workspaces, etc. This separation of persistent and work-in-progress data has significant benefits that make edge servers perform optimally for certain use cases.

When a new edge server is deployed for the first time, it is "seeded" with a special seed checkpoint from the master server. This is done using the SDP `edge_dump.sh` script.

Edge servers need to be reseeded in certain circumstances. When an edge server is reseeded, the latest persistent history from the master server is combined with the latest work-in-progress data from the edge server.

Some occasions that require reseeding include:

- When changing the scope of replication filtering, i.e. if the `*DataFilter` fields of the server spec are changed.
- In some recovery situations involving hardware or other infrastructure failure.
- When advised by Perforce Support.

An article [Edge Server Metadata Recovery](#) discusses the manual process in detail. The process outlined in this article is implemented in the SDP with two scripts, `edge_dump.sh` and `recover_edge.sh`.

Key aspects of this implementation:

- No downtime is required for the master server process.
- Downtime for the edge to be reseeded is required. This is kept to a minimum.

10.5. Edge Reseed Scenario

In this sample scenario, an edge server needs to be reseeded.

Sample details about this scenario:

- The SDP instance is 1.
- The `perforce` operating system runs the `p4d` process on all machines.
- The `perforce` user's `~/.bashrc` ensures that the shell environment is set automatically on login, by doing: `source /p4/common/bin/p4_vars 1`
- The master server has a ServerID of `master.1` and runs on the machine `bos-helix-01`.
- The edge server has a ServerID of `p4d_edge_syd` and runs on the machine `syd-helix-04`.
- Both the master and edge server are online and actively in use at the start of processing.
- Users of the edge server to be reseeded have been notified about a planned outage.
- No outage is planned or necessary for the master server
- SSH keys are setup for the `perforce` user.

10.5.1. Step 0: Preflight Checks

Make sure the start state is healthy.

As `perforce@bos-helix-01` (the master):

```
verify_sdp.sh 1 -online
```

As `perforce@syd-helix-04` (the edge):

```
verify_sdp.sh 1
```

10.5.2. Step 1: Create New Edge Seed Checkpoint

On the master server, create a new edge seed checkpoint using `edge_dump.sh`. This will contain recent persistent history from the master.

This process uses the `offline_db` rather than `P4ROOT`, so no downtime is needed.

Creating an edge seed requires that the `offline_db` directory not be interfered with. The `daily_checkpoint.sh` script runs in the crontab of the `perforce` user on the master, and that script must not be run when `edge_dump.sh` runs. Ensure that `edge_dump.sh` is run at a time when it won't conflict with the operation of `daily_checkpoint.sh`. If checkpoints take many hours, consider disabling the crontab for `daily_checkpoint.sh` by commenting it out of the crontab until `edge_dump.sh` completes — but don't forget to re-enable it afterward!

Create the edge seed like so, as `perforce@bos-helix-01` (the master):

```
nohup /p4/common/bin/p4master_run 1 edge_dump.sh 1 p4d_edge_syd < /dev/null >
/p4/1/logs/dump.log 2>&1 &
```

Then monitor until completion with:

```
tail -f $(ls -t $LOGS/edge_dump.*.log | head -1)
```

The edge seed will appear as a file looking something like:

```
/p4/1/checkpoints/p4_1.edge_syd.seed.2035.gz
/p4/1/checkpoints/p4_1.edge_syd.seed.2035.gz.md5
```

When the `.md5` file appears, the edge seed checkpoint is complete.

Notes:

- The `nohup` at the beginning of the command and the `&` at the end ensure this process will continue to run even if the terminal window in which the command was executed disconnects.

10.5.3. Step 2: Transfer Edge Seed

Transfer the edge seed from the master to the edge like so, as `perforce@bos-helix-01` (the master):

```
scp -p /p4/1/checkpoints/p4_1.edge_syd.seed.2035.gz syd-helix-04:/p4/1/checkpoints/.
scp -p /p4/1/checkpoints/p4_1.edge_syd.seed.2035.gz.md5 syd-helix-
04:/p4/1/checkpoints/.
```

10.5.4. Step 3: Reseed the Edge

Reseed the edge. As `perforce@syd-helix-04` (the edge):

```
nohup /p4/common/bin/run_if_edge.sh 1 recover_edge.sh 1
/p4/1/checkpoints/p4_1.edge_syd.seed.2035.gz < /dev/null > /p4/1/logs/rec.log 2>&1 &
```

Notes:

- The `offline_db` of the edge server is removed at the start of processing, but is replaced at the end.
- It is safe for the `p4d` process of the edge server to be up and running when this process starts. If it is up at the start of processing, it will be shutdown by the `recovered_edge.sh`, but not immediately. The script allows the `p4d` service to remain in use while the edge seed checkpoint from the master is replayed into the `offline_db`.
- After the edge seed checkpoint has been replayed, the `p4d` service is shutdown, and then the process of combining persistent and work-in-progress data commences, the essence of the reseed operation.
- After the edge reseed is complete, the `p4d` process is started. It will then start replicating new data from the master since the time of the edge seed checkpoint creation. The `p4d` service may

hang and be unresponsive for several minutes after it is started. If you choose to monitor closely, when a `p4 pull -lj` on the edge indicates it has caught up to the master, the service is safe to use again.

- The `recover_edge.sh` script continues to run after the service is back online, as it rebuilds the `offline_db` of the edge server.
- On the edge server, the edge server's regular checkpoints land in `/p4/1/checkpoints.edge_syd`. The `/p4/1/checkpoints` folder is used only for holding edge seed checkpoints transferred from the master.
- Typically, all steps described in the process are done on the same day. However, it is OK if the `edge_dump.sh`, seed checkpoint transfer, and `recover_edge.sh` with some time lag between the major steps, typically measured in journal rotations or simply days, with incremental impact on the duration of the recovery step, and so long as the edge seed is not so far behind that the master no longer has numbered journals to feed the edge once it starts.

Reseeding requires that the `offline_db` directory not be interfered with. The `daily_checkpoint.sh` script runs in the crontab of the `perforce` user on the edge server, and that script must not be run when `recover_edge.sh` runs. Ensure that `recover_edge.sh` is run at a time when it won't conflict with the operation of `daily_checkpoint.sh`. If checkpoints take many hours, consider disabling the crontab for `daily_checkpoint.sh` by commenting it out of the crontab until `recover_edge.sh` completes — but don't forget to re-enable it afterward!

This sample procedure does not illustrate using a `p4broker` service to broadcast a "Down for maintenance" message on the edge server. If your SDP installation uses `p4brokers` on `p4d` server machines, they can be used to prevent regular users from attempting to access the edge server during the processing of `recover_edge.sh`. This can help prevent users from experiencing a hang, for example, in the time after the edge `p4d` process starts but before it catches up to the master.

Appendix A: SDP Package Contents and Planning

The directory structure of the SDP is shown below in Figure 1 - SDP Package Directory Structure. This includes all SDP files, including documentation and sample scripts. A subset of these files are deployed to server machines during the installation process.

```
sdp
  doc
  Server (Core SDP Files)
    Unix
      setup (Unix-specific setup)
      p4
        common
          bin (Backup scripts, etc)
          triggers (Example triggers)
        config
        etc
          cron.d
          init.d
          systemd
        lib
        test
      setup (cross platform setup - typemap, configure, etc)
      test (automated test scripts)
```

Figure 1 - SDP Package Directory Structure

A.1. Volume Layout and Server Planning

Figure 2: SDP Runtime Structure and Volume Layout, viewed from the top down, displays a Perforce *application* administrator's view of the system, which shows how to navigate the directory structure to find databases, log files, and versioned files in the depots. Viewed from the bottom up, it displays a Perforce *system* administrator's view, emphasizing the physical volume where Perforce data is stored.

A.1.1. Memory and CPU

Make sure the server has enough memory to cache the **db.rev** database file and to prevent the server from paging during user queries. Maximum performance is obtained if the server has enough memory to keep all of the database files in memory. While the p4d process itself is frugal with system resources such as RAM, it benefits from an excess of RAM due to modern operating systems using excess RAM as file I/O cache. This is to the great benefit of p4d, even though the p4d process itself may not be seen as consuming much RAM directly.

Below are some approximate guidelines for allocating memory.

- 1.5 kilobyte of RAM per file revision stored in the server.
- 32 MB of RAM per user.

INFO: When doing detailed history imports from legacy SCM systems into Perforce, there may be many revisions of files. You want to account for (total files) x (average number of revisions per file) rather than simply the total number of files.

Use the fastest processors available with the fastest available bus speed. Faster processors are typically more desirable than a greater number of cores and provide better performance since quick bursts of computational speed are more important to Perforce's performance than the number of processors. Have a minimum of two processors so that the offline checkpoint and back up processes do not interfere with your Perforce server. There are log analysis options to diagnose underperforming servers and improve things. Contact Perforce Support/Perforce Consulting for details.

A.1.2. Directory Structure Configuration Script for Linux/Unix

This script describes the steps performed by the `mkdirs.sh` script on Linux/Unix platforms. Please review this appendix carefully before running these steps manually. Assuming the three-volume configuration described in the Volume Layout and Hardware section are used, the following directories are created. The following examples are illustrated with "1" as the server instance number.

<i>Directory</i>	<i>Remarks</i>
<code>/p4</code>	Must be under root (/) on the OS volume
<code>/hxdepots/p4/1/bin</code>	Files in here are generated by the <code>mkdirs.sh</code> script.
<code>/hxdepots/p4/1/depots</code>	
<code>/hxdepots/p4/1/tmp</code>	
<code>/hxdepots/p4/common/config</code>	Contains <code>p4_<instance>.vars</code> file, e.g. <code>p4_1.vars</code>
<code>/hxdepots/p4/common/bin</code>	Files from <code>\$SDP/Server/Unix/p4/common/bin</code> .
<code>/hxdepots/p4/common/etc</code>	Contains <code>init.d</code> and <code>cron.d</code> .
<code>/hxlogs/p4/1/logs/old</code>	
<code>/hxmetadata2/p4/1/db2</code>	Contains offline copy of main server databases (linked by <code>/p4/1/offline_db</code>).
<code>/hxmetadata1/p4/1/db1/save</code>	Used only during running of <code>refresh_P4ROOT_from_offline_db.sh</code> for extra redundancy.

Next, `mkdirs.sh` creates the following symlinks in the `/hxdepots/p4/1` directory:

<i>Link source</i>	<i>Link target</i>	<i>Command</i>
<code>/hxmetadata1/p4/1/db1</code>	<code>/p4/1/root</code>	<code>ln -s /hxmetadata1/p4/1/root</code>

<i>Link source</i>	<i>Link target</i>	<i>Command</i>
/hxmetadata2/p4/1/db2	/p4/1/offline_db	ln -s /hxmetadata1/p4/1/offline_db
/hxlogs/p4/1/logs	/p4/1/logs	ln -s /hxlogs/p4/1/logs

Then these symlinks are created in the /p4 directory:

<i>Link source</i>	<i>Link target</i>	<i>Command</i>
/hxdepots/p4/1	/p4/1	ln -s /hxdepots/p4/1 /p4/1
/hxdepots/p4/common	/p4/common	ln -s /hxdepots/p4/common /p4/common

Next, `mkdirs.sh` renames the Perforce binaries to include version and build number, and then creates appropriate symlinks.

A.1.3. P4D versions and links

The versioned binary links in `/p4/common/bin` are as below.

For the example of <instance> 1 we have:

```
ls -l /p4/1/bin
p4d_1 -> /p4/common/bin/p4d_1_bin
```

The structure is shown in this example, illustrating values for two instances, with instance #1 using p4d release 2018.1 and instance #2 using release 2018.2.

In `/p4/1/bin`:

```
p4_1 -> /p4/common/bin/p4_1_bin
p4d_1 -> /p4/common/bin/p4d_1_bin
```

In `/p4/2/bin`:

```
p4_2 -> /p4/common/bin/p4_2
p4d_2 -> /p4/common/bin/p4d_2
```

In `/p4/common/bin`:

```
p4_1_bin -> p4_2018.1_bin
p4_2018.1_bin -> p4_2018.1.685046
p4_2018.1.685046
```

```
p4_2_bin -> p4_2018.2_bin
```

```
p4_2018.2_bin -> p4_2018.2.700949
p4_2018.2.700949
```

```
p4d_1_bin -> p4d_2018.1_bin
p4d_2018.1_bin -> p4d_2018.1.685046
p4d_2018.1.685046
```

```
p4d_2_bin -> p4d_2018.2_bin
p4d_2018.2_bin -> p4d_2018.2.700949
p4d_2018.2.700949
```

The naming of the last comes from:

```
./p4d_2018.2.700949 -V
```

```
Rev. P4D/LINUX26X86_64/2018.2/700949 (2019/07/31).
```

So we see the build number `p4d_2018.2.700949` being included in the name of the p4d executable.

Although this link structure may appear quite complex, it is easy to understand, and it allows different instances on the same server host to be running with different patch levels, or indeed different releases. And you can upgrade those instances independently of each other which can be very useful.

A.1.4. Case Insensitive P4D on Unix

By default `p4d` is case sensitive on Unix for filenames and directory names etc.

It is possible and quite common to run your server in case insensitive mode. This is often done when Windows is the main operating system in use on the client host machines.

In "case insensitive" mode, that means that you should ALWAYS execute `p4d` with the flag `-C1` (or you risk possible table corruption in some circumstances).

The SDP achieves this by executing a simple Bash script which (for instance 1) is `/p4/1/bin/p4d_1` with contents:

```
#!/bin/bash
P4D="/p4/common/bin/p4d_1_bin"
exec $P4D -C1 "$@"
```

So the above will ensure that `/p4/common/bin/p4d_1_bin` (for instance 1) is executed with the `-C1` flag.

As noted above, for case sensitive servers, `p4d_1` is normally just a link:

```
/p4/1/bin/p4d_1 -> /p4/common/bin/p4d_1_bin
```

Note for an instance `alpha` (not `1`), the file would be `/p4/alpha/bin/p4d_alpha` with contents:

```
#!/bin/bash  
P4D="/p4/common/bin/p4d_alpha_bin"  
exec $P4D -C1 "$@"
```

Appendix B: The journalPrefix Standard

The Perforce Helix configurable `journalPrefix` determines where the active journal is rotated to when it becomes a numbered journal file during the journal rotation process. It also defines where checkpoints are created.

In the SDP structure, the `journalPrefix` is set so that numbered journals and checkpoints land on the `/hxdepots` volume. This volume contains critical digital assets that should be reliably backed up and should have sufficient storage for large digital assets such as checkpoints.

B.1. SDP Scripts that set `journalPrefix`

The SDP `configure_new_server.sh`, which applies SDP standards to fresh new `p4d` servers, sets the `journalPrefix` for the master server according to this standard.

The SDP `mkrep.sh` script, which creates new replicas, sets `journalPrefix` for replicas according to this standard.

The SDP `mkdirs.sh` script, which initializes the SDP structure, creates a directory structure for checkpoints based on the `journalPrefix`.

B.2. First Form of `journalPrefix` Value

The first form of the `journalPrefix` value applies to the master server's metadata set. This value is of this form, where `N` is replaced with the SDP instance name:

```
/p4/N/checkpoints/p4_N
```

If the SDP instance name is the default `1`, then files with a `p4_1` prefix would be stored in the `/p4/1/checkpoints` directory on the filesystem. Journal files in that directory would have names like `p4_1.jnl.320` and checkpoints would have names like `p4_1.ckp.320.gz`.

This `journalPrefix` value and the corresponding `/p4/1/checkpoints` directory should be used for the master server. It should also be used for any replica that is a valid failover target for the master server. This includes all *completely unfiltered* replicas of the master, such as `standby` and `forwarding-standby` replicas with a `P4TARGET` value referencing the master server.

A `standby` replica, also referred to as a `journalcopy` replica due to the underlying replication mechanisms, cannot be filtered. Standby replicas are commonly deployed for High Availability (HA) and Disaster Recovery (DR) purposes.

B.2.1. Detail on "Completely Unfiltered"

A "completely unfiltered" replica is one in which:

- None of the `*DataFilter` fields in the replica's server spec are used

- The `p4 pull` command configured to pull metadata from the the replica's `P4TARGET` server, as defined in the replica's `startup.N` configurable, does not use filtering options such as `-T`.
- The replica is not an Edge server (i.e. one with a `Services` value in the server spec of `edge-server`.) Edge servers are filtered by their vary nature, as they exclude various database tables from being replicated.
- The replica's seed checkpoint was created without the `-P ServerID` flag to `p4d`. The `-P` flag is used when creating seed checkpoints for filtered replicas and edge servers.
- The replica's `P4TARGET` server references something other than the master server, such as an edge server.

B.3. Second Form of journalPrefix Value

A second form of the `journalPrefix` is used when the replica is filtered, including edge servers. The second form of the `journalPrefix` value incorporates a shortened form of the `ServerID` to indicate that the data set is specific to that `ServerID`. Because the metadata differs from the master, checkpoints for edge servers and filtered replicas are stored in a different directory, and use a prefix that identifies them as separate and divergent from the master's data set. This second form allows checkpoints from multiple edge servers or filtered replicas to be stored on an shared (e.g. NFS-mounted) `/hxdepots` volume.

The second form of `journalPrefix` is also used if the `/hxdepots` volume, on which checkpoints are stored, is shared (as indicated when the replica's `lbr.replication` value is set to a value of `shared`).

Filtered replicas are a strict subset of the master server's metadata. Edge servers filter some database tables from the master, but also have their own independent metadata (mainly workspace metadata) that varies from the master server and is potentially larger than the master's data set for some tables.

The "shortened form" of the `ServerID` removes the `p4d_` prefix (per [Appendix C, Server Spec Naming Standard](#)). So, for example an edge server with a `ServerID`` of `p4d_edge_uk` would use just the `edge_uk` portion of the `ServerID` in the `journalPrefix`, which would look like:

```
/p4/N/checkpoints.edge_uk/p4_N.edge_uk
```

If the SDP instance name is the default `1`, then files with a `p4_1.edge_uk` prefix would be stored in the `/p4/1/checkpoints.edge_uk` directory on the filesystem. Journal files in that directory would have names like `p4_1.edge_uk.320.jnl` and checkpoints would have names like `p4_1.edge_uk.320.ckp.gz`.

B.4. Scripts for Maintaining the offline_db

The following SDP scripts help maintain the `offline_db`:

- `daily_checkpoint.sh`: The `daily_checkpoint.sh` is used on the master server. When run on the master server, this script rotates the active journal to a numbered journal file, and then maintains the master's `offline_db` using the numbered journal file immediately after it is

rotated.

The `daily_checkpoint.sh` is also used on edge servers and filtered replicas. When run on edge servers and filtered replicas, this script maintains the replica's `offline_db` in a manner similar to the master, except that the journal rotation is skipped (as that can be done only on the master).

- `sync_replica.sh`: The SDP `sync_replica.sh` script is intended to be deployed on unfiltered replicas of the master. It maintains the `offline_db` by copying (via `rsync`) the checkpoints from the master, and then replays those checkpoints to the local `offline_db`. This keeps the `offline_db` of the replica current, which is good to have should the replica ever need to take over for the master.

INFO: For HA/DR and any purpose where replicas are not filtered, replicas of type `standby` and `forwarding-standby` should displace replicas of type `replica` and `forwarding-replica`.

B.5. SDP Structure and `journalPrefix`

On every server machine with the SDP structure where a `p4d` service runs (excluding broker-only and proxy-only hosts), a structure like the following should exist for each instance:

- A `/hxdepots/p4/N/checkpoints` directory
- In `/p4/N`, and symlink `checkpoints` that links to `/hxdepots/p4/N/checkpoints`, such that it can be referred to as `/p4/N/checkpoints`.

In addition, edge servers and filtered replicas will also have a structure like the following for each instance that runs an edge server or filtered replica:

- A `/hxdepots/p4/N/checkpoints.ShortServerID` directory
- In `/p4/N`, and symlink `checkpoints.ShortServerID` that links to `/hxdepots/p4/N/checkpoints.ShortServerID`, such that it can be referred to as `/p4/N/checkpoints.ShortServerID`.

The SDP `mkdirs.sh` script, which sets up the initial SDP structure, initializes this structure on initial install.

B.6. Replicas of Edge Servers

As edge servers have unique data, they are commonly deployed with their own `standby` replica with a `P4TARGET` value referencing a given edge server rather than the master. This enables faster recovery option for the edge server.

As a special case, a `standby` replica of an edge server should have the same `journalPrefix` value as the edge server it targets. Thus, the `ServerID` baked into the `journalPrefix` of a replica of an edge is the `ServerID` of the target edge server, not the replica.

So for example, an edge server with a `ServerID` of `p4d_edge_uk` has a `standby` replica with a `ServerID` of `p4d_ha_edge_uk`. The `journalPrefix` of that edge should be the same as the edge server it targets, e.g.

```
/p4/1/checkpoints.edge_uk/p4_1.edge_uk
```

B.7. Goals of the **journalPrefix** Standard

Some design of goals this standard:

- Make it so the `/p4/N/checkpoints` folder is reserved to mean checkpoints created from the master server's full metadata set.
- Make the `/p4/N/checkpoints` folder be safe to rsync from the master to any machine in the topology (as may be needed in certain recovery situations for replicas and edge servers).
- Make it so the SDP `/hxdepots` volume can be NFS-mounted across multiple SDP machines safely, such that two or more edge servers (or filtered replicas) could share versioned files, while writing to separate checkpoints directories on a per-ServerID basis.
- Support all replication uses cases, including support for 'Workspace Servers', a name referring to a set of edge servers deployed in in the same location, typically sharing `/hxdepots` via NFS. Use of Workspace Servers can be used to scale Helix Core horizontally for massive user bases (typically several thousand users).

Appendix C: Server Spec Naming Standard

Perforce Helix server specs identify various Helix servers in a topology. Servers can be p4d servers (master, replicas, edges), p4broker, p4p, etc. This standard defines the standard for the server spec names.

C.1. General Form

The general form of a server spec name is:

```
<HelixServerTag>_<ReplicaTypeTag>[<N>]_<SiteTag>
```

C.1.1. Helix Server Tags

The `HelixServerTag_` is one of:

- **p4d**: for a Helix Core server (including all [distributed architecture](#) usages such as master/replica/edge).
- **p4broker**: A [Helix Broker](#)
- **p4p**: A [Helix Proxy](#)
- **gconn**: Helix4Git (H4G) Connector
- **swarm**: Helix Swarm

As a special case, the *HelixServerTag* is omitted for the ServerID of the master server spec.

C.1.2. Replica Type Tags

The *ReplicaType* is one of:

- **master.<instance>**: The single master-commit server for a given SDP instance. SDP instance names are included in the ServerID for the master, as they intended to be unique within an enterprise. They must be unique to enable certain cross-instance sharing workflows, e.g. using remote depots and Helix native DVCS features.
- **ha**: High Availability. This indicates a replica that was specifically intended for HA purposes and for use with the **p4 failover** command. It further implies the following:
 - The Services field value is **standby**.
 - The **rpl.journalcopy.location=1** configurable is set, optimized for SDP deployment.
 - The replica is not filtered in any way: No usage of the **-T** flag to **p4 pull** in the replicas startup.*N* configurables, and no usage of ***DataFilter** fields in the server spec.
 - Versioned files are replicated (with an **lbr.replication** value of **readonly**).
 - An HA replica is assumed to be geographically near its P4TARGET server, which can be a master server or an edge server.

- It may or may not use the **mandatory** option in the server spec. The **ha** tag does not indicate whether the **mandatory** option is used (as this is more transient thing not suitable for baking into a server spec naming standard).
- **ham**: A **ham** replica is the same as an **ha** replica except it does not replicate versioned files. Thus is a *metadata-only* replica that shares versioned files with its P4TARGET server (master or edge) with an **lbr.replication** value of **shared**.
- **fr**: Forwarding Replica (unfiltered) that replicates versioned files.
- **frm**: Forwarding replica (unfiltered) that shares versioned files with its target server rather than replicating them.
- **fs**: Forwarding Standby (unfiltered) that replicates versioned files. This is the same as an **ha** server, except that it is not necessarily expected to be physically near its P4TARGET server. This could be suited for Disaster Recovery (DR) purposes.
- **fsm**: Forwarding standby (unfiltered) that shares versioned files with its target server rather than replicating them. This is the same as a **ham**, except that it is not necessarily expected to be physically near its P4TARGET server.
- **ffr**: Filtered Forwarding Replica. This replica uses some of filtering, such as usage of ***DataFilter** fields of the server spec or **-T** flag to **p4 pull** in the replicas **startup.<N>** configurables. Filtered replicas are not viable failover targets, as the filtered data would be lost.
- **ro** - Read Only replica (unfiltered), replicating versioned files).
- **rom** - Read Only metadata-only replica (unfiltered, sharing versioned files).
- **edge** - Edge servers. (As edge servers are filtered by their nature, they are not valid failover targets).

C.1.2.1. Replication Notes

If a replica does not need to be filtered, we recommend using **journalcopy** replication, i.e. using a replica with a **Services:** field value of **standby** or **forwarding-standby**. Only use non-journalcopy replication when using filtered replicas (and edge servers where there is no choice).

Some general tips:

- The **ha**, **ham** replicas are preferred for High Availability (HA) usage.
- The **fs** and **ro** replicas are preferred for Disaster Recovery (DR) usage.
- Since DR implies the replica is far from its master, replication of archives (rather than sharing e.g. via NFS) may not be practical, and so **rom** replicas don't have common use cases.
- The **fr** type replica is obsolete, and should be replaced with **fs** (using **journalcopy** replication).

C.1.3. Site Tags

The site tag needs to distinguish the data centers used by a single enterprise, and so generally short tag names are appropriate. See [Section 6.3.4.1, "SiteTags.cfg"](#)

Each site tag may be understood to be a true data center (Tier 1, Tier 2, etc.), a computer room, computer closet, or reserved space under a developer's desk. In some cases organizations will

already have their own familiar site tags to refer to different sites or data centers; these can be used.

In public cloud deployments, the public cloud provider's region names can be used (e.g. `us-east-1`), or an internal short form (e.g. `awsnva1` for the AWS us-east-1 data center in Northern Virginia, USA).

As a special case, the `<SiteTag>` is omitted for the master server spec.

C.2. Example Server Specs

Here are some sample server spec names based on this convention:

- `master.1`: A master server for SDP instance 1.
- `p4d_ha_chi`: A High Availability (HA) server, suitable for use with `p4 failover`, located in Chicago, IL.
- `p4d_ha2_chi`: A second High Availability server, suitable for use with `p4 failover`, located in Chicago, IL.
- `p4d_ffr_pune`: A filtered forwarding replica in Pune, India.
- `p4d_edgeblr`: An edge server located in Bangalore, India.
- `p4d_ha_edgeblr`: An HA server with P4TARGET pointing to the edge server in Bangalore, India.
- `p4d_edge3_awsnva`: A 3rd edge server in AWS data center in the us-east-1 (Northern Virginia) region.

C.3. Implications of Replication Filtering

Replicas that are filtered in any way are not viable candidate servers to failover to, because any filtered data would be lost.

C.4. Other Replica Types

The naming convention intentionally does not account for all possible server specs available with p4d. The standard accounts only for the distilled list of server spec types supported by the SDP `mkrep.sh` script, which are the most useful and commonly used ones.

C.5. The SDP `mkrep.sh` script

The SDP script `mkrep.sh` adheres to this standard. For more information on creating replicas with this script. See: [Section 6.3.4, "Using mkrep.sh"](#).

Appendix D: Frequently Asked Questions

This FAQ lists common questions about the SDP with answers.

D.1. How do I tell what version of the SDP I have?

First, try the standard check. See: [Section 1.3, “Checking the SDP Version”](#).

If that does not display the SDP version, as may happen with older SDP installations, run the SDP Health Check, which will report the correct version reliably. See: [Appendix H, SDP Health Checks](#).

D.2. How do I change super user password?

There are two critical accounts to be aware of:

- The UNIX/Linux operating system user account with a password managed by the operating system of the machine, referred to as the OSUSER.
- The Perforce application super user with a password in the Perforce database. The SDP standard shell environment sets P4USER to refer to the super user.

The user account name `perforce` is the default for both OSUSER and P4USER, but they can have different values. The OSUSER applies to the server machine, while the P4USER can vary on a per-instance basis.

Some admins choose to use the same password for the `perforce` OSUSER and P4USER (for convenience and to reduce confusion), and then do routine rotations of both passwords (for enhanced security).

The Perforce application super user should always use Perforce password management, even if other accounts are configured to use LDAP, SSO, or some other authentication method.

To change the OSUSER, use your standard operating system commands. This may be the `passwd` command, but may be different depending on your operating system and other factors.

The following describes how to change the Perforce application super user password.

Step 1. Get a maintenance Window

Plan to do this work in a maintenance window. The procedure can cause disruption if any triggers or extensions rely on a valid ticket for your application super user. Also, much automation such as the SDP `daily_checkpoint.sh` script rely on having a valid ticket.

If you are fully aware of all the ways the password is used and thus the potential impacts, you can do the work outside of a maintenance window. Changing the password can disrupt triggers, extensions, and various automation, but will not have any impact on Helix Core service itself.

Step 2. Pick a Password

Select your new password. Depending on your local policy, you may manually create a password, generate one, and possibly store it in a vault of some kind.

Step 3. Login as the OSUSER

Login as the OSUSER (e.g. `perforce`), and ensure the standard SDP shell environment is set.

If the OSUSER shell environment files `~/.bash_profile` and `~/.bashrc` are set correctly, this step is done just by logging into the `perforce` OSUSER account.

Step 4. Get the current password from the admin password file. The shell variable `$SDP_ADMIN_PASSWORD_FILE` contains the path to the password file for the current instance, something like `/p4/common/config/.p4passwd.p4_N.admin`. Do

```
cat $SDP_ADMIN_PASSWORD_FILE
```

Take note of the current/old password.

Step 5. Put the new password in the admin password file.

Step 7. Do:

```
p4 passwd
```

Provide the old and new password as prompted.

Step 6. Call the `p4login` script to exercise the new password file:

```
p4login -v
```

Confirm you have a valid ticket afterward with:

```
p4 login -s
```

Step 7. Copy the password file to any and all replica and edge server machines.

Step 8. On each replica and edge, login as `perforce` and also do `p4login -v` and `p4 login -s`.

D.3. Can I remove the perforce user?

No. This account is required for critical operations like checkpoints for backup.

This account need not occupy a licensed seat. Once a Helix Core server becomes

licensed, you can fill out the [Helix Core Request for Background User](#) form to request up to 3 "background users" to support background automation tasks. This accounts for the `perforce` super user, a `swarm` user, and typically one named something like `builder` for automated builds.

D.4. Can I clone a VM to create a standby replica?

Yes, cloning a virtual machine (VM) of a Helix Core commit server is a great way to simplify the process of creating a standby replica of the commit server. Similarly, cloning an edge server is useful in creating a standby replica of the edge.

Cloning can be done with various technologies and in cloud and on-prem environments. For example, in AWS, creating an AMI of an EC2 instance (i.e. a virtual machine) is just different terminology for creating a clone of the virtual machine. Azure, GCP, and other clouds have similar concepts and capabilities, as do on-prem virtual infrastructure such as VMware ESX servers. Even non-virtual infrastructure tools exist for cloning bare metal server machines.

Nothing needs to change other than the `server.id` file whether the machine you're cloning is a commit server (to make a standby of the commit) or an edge (to make a standby of the edge). There is a slight SDP structure difference between an commit and an edge—an edge will have a `/hxdepots/p4/N/checkpoints.edge_SITE` directory and `/p4/N/checkpoints.edge_SITE` symlink to it. As long as you clone the machine that you're making a standby of, be it commit or edge, you'll have the correct structure on the standby.

While nothing should need to change, there are a few things to double check before initiating the cloning process:

- Check that the SDP Instance Vars file, `/p4/common/config/p4_N.vars` has correct values for **P4MASTERHOST** and **P4MASTER_ID**.
- The **P4MASTER_ID** must be the `server.id` of the commit server, always, and that will be the same regardless of what machine you're on. The **P4MASTERHOST** should be a DNS name for the commit server that works—i.e. that valid to reference from the standby server after cloning. Using the same DNS name used by regular users is preferred—it can be an FQDN or a short name depending on how DNS is setup locally. If DNS isn't available in the server environment (as is sometimes the case), Plan B for setting **P4MASTERHOST** is to still use the same DNS that users know, but to add an `/etc/hosts` entry ("hack?") on the standby server machine after cloning so that the DNS name works on the standby to reference the commit server. Plan C, which we strongly advise against but do support, is to use an IP address for the **P4MASTERHOST** value. Plan A is preferred because Plans B and C require the admin who executes failover to be aware of the "hacks"—`/etc/hosts` entry or using an IP address—to be accounted for in the failover procedure.

The general idea is that `/p4/common` structure in the SDP should be *common* across all Helix Core server machines in your fleet. Even on the standby replica, the **P4MASTER_ID** and **P4MASTERHOST** values be exactly the same as on the commit. Cloning the machine is the best way to do it. It's also nice to have a reasonably current set of archives, and nice to ensure all those little SDP config bits are correct.

Here is a sample procedure of cloning a machine to create a standby replica.

Step 1. Verify `P4MASTER_ID` and `P4MASTERHOST` settings are correct.

Step 2. Use `mkrep.sh` to create your standby server. See: [Section 6.3.4, “Using mkrep.sh”](#).

Step 3. Run `p4 admin journal`. (Digression: Use `p4 admin journal` command if you’re creating a standby or unfiltered edge or replica, but use the `rotate_journal.sh` script instead if you’re creating a filtered edge or filtered forwarding replica, where *filtered* here means using the `*DataFilter` fields in the server spec and/or using `-T` option to the configured `startup.N` thread that does the metadata pull for the ServerID of the new server.)

Step 4. Clone the VM.

Step 5. Start the new VM after the cloning operation. For example, if in AWS, launch an EC2 instance from the AMI.

Step 6. Stop the `p4d_N` (and `p4broker_N`) services if running.

Step 7. Use `hostname -I` to get the local/private IP, and request a new license file for that IP—but don’t wait for it.

Step 8. Remove the `$P4ROOT/license` file.

Step 9. Remove the `$P4ROOT/server.id` file.

Step 10. Load the latest checkpoint and numbered journal, and then pull recent archives, e.g. with a command like this sample:

```
nohup load_checkpoint.sh /p4/1/checkpoints/p4_1.ckp.50.gz
/p4/1/checkpoints/p4_1.jnl.50 -s p4d_ha_bos -l -r -b -y -verify default < /dev/null >
/p4/1/logs/load.log 2>&1 &
```

That `load_checkpoint.sh` does the rest. It stops `p4d` and `p4broker` services (just in case you forgot), clears `P4ROOT`, moves `P4LOG` and `P4JOURNAL` aside if they exist (which they would after a cloning situation), puts the new correct `server.id` file in place, reloads from the latest checkpoint and numbered journal (that are sure to have the very latest data due to the `p4 admin journal` done above just before the cloning), does a `p4d -xu` (just in case it’s needed, but shouldn’t be in this situation), starts the service, and then kicks off a `p4 verify -t` command on all depots to pull over any missing files from the commit.

The above procedure is merely a sample. Certain details, such as the handling of license files, may vary from one site to another.

Appendix E: Troubleshooting Guide

This appendix lists problems sometimes encountered by SDP users, with guidance on how to analyze and resolve each issue.

Do not hesitate to contact consulting@perforce.com if additional assistance is required.

E.1. Daily_checkpoint.sh fails

1. Check the output of the log file and look for errors:

```
less /p4/1/logs/checkpoint.log
```

Possibilities include:

- Errors from `verify_sdp.sh` - should be self explanatory.
 - Note that it is possible to edit `/p4/common/config/p4_1.vars` and set the value of `VERIFY_SDP_SKIP_TEST_LIST` to include any tests you consider should be skipped - don't overdo this!
- See next section

E.1.1. Last checkpoint not complete. Check the backup process or contact support.

If this error occurs it means the script has found a "semaphore" file which is used to prevent multiple checkpoints running at the same time. This file is (for instance 1) `/p4/1/logs/ckp_running.txt`.

Check if there is a current process running:

```
ps aux | grep daily_checkpoint
```

If you are CERTAIN that there is no checkpoint process running, then you can delete this file and re-run `daily_checkpoint.sh` (or allow it to be run via nightly crontab). If in doubt, contact support!

E.2. Replication appears to be stalled

This can happen for a variety of reasons, most commonly:

- Service user is not logged in to the parent
 - Or there is a problem with ticket or ticket location
- Configurables are incorrect (`p4 configure show allservers`)

- Network connectivity to upstream parent
 - A problem with state file
1. Check the output of `p4 pull -lj`, e.g. this shows all is working well:

```
$ p4 pull -lj
Current replica journal state is:      Journal 1237, Sequence 2680510310.
Current master journal state is:      Journal 1237, Sequence 2680510310.
The statefile was last modified at:   2022/03/29 14:15:16.
The replica server time is currently:  2022/03/29 14:15:18 +0000 GMT
```

E.2.1. Resolution

1. This example shows a password error for the service user:

```
$ p4 pull -lj
Perforce password (P4PASSWD) invalid or unset.
Perforce password (P4PASSWD) invalid or unset.
Current replica journal state is:      Journal 1237, Sequence 2568249374.
Current master journal state is:      Journal 1237, Sequence -1.
Current master journal state is:      Journal 0,      Sequence -1.
The statefile was last modified at:   2022/03/29 13:05:46.
The replica server time is currently:  2022/03/29 14:13:21 +0000 GMT
```

- a. In case of a password error, try logging in again:

```
p4login -v 1 -service
p4 pull -lj
```

- b. If the above reports an error, then copy and paste the command it shows as executing and try it manually, for example (adjust the server/user ids):

```
/p4/1/bin/p4_1 -p p4master:1664 -u p4admin -s login svc_p4d_edge_ldn
```

If the above is not successful:

3. Review output of `verify_sdp.sh`:

```
/p4/common/bin/verify_sdp.sh 1
grep Error /p4/1/logs/verify_sdp.log
```

- a. Check for errors in the resulting log file:

```
grep Error /p4/1/logs/verify_sdp.log
```

4. Check for errors in the p4d log file:

```
grep -A4 error: /p4/1/logs/log | less
```

5. Check permissions on the tickets file (env var `$P4TICKETS`):

```
ls -al $P4TICKETS
```

e.g.

```
ls -al /p4/1/.p4tickets
```

E.2.2. Make Errors Visible

If the above doesn't help, then make errors visible/easy to find, assuming instance **1** - run this **on the replica (not commit!)**:

```
sudo systemctl stop p4d_1
cd /p4/1/logs
mv log log.old
sudo systemctl start p4d_1
grep -A4 error: log | less
```

Due to shortened log file, any errors should be easily found. Ask for help (email support-helix-core@perforce.com) if not obvious.

E.2.3. Remove state file

Files `state` and `statejcopy` can usually be removed - let the server work out its current state. If you want to know current journal counter for replica:

```
p4d -r /p4/1/root -k db.counters -jd - 2>/dev/null | grep @journal@ | cut -d '@' -f 8
```

If there is a problem with being able to pull over an old journal which no longer exists on the master you may need to reseed the replica!

```
sudo systemctl stop p4d_1
cd /p4/1/root
mv state* save/
cd /p4/1/logs
```

```
[[ -d save ]] || mkdir save          # Create if doesn't exist
mv journal* save/
sudo systemctl start p4d_1
```

E.3. Archive pull queue appears to be stalled

This manifests as the output of `p4 pull -ls` showing an unchanging number of files in the queue - no progress is being made.

```
$ p4 pull -ls
File transfers: 3 active/29 total, bytes: 2338 active/25579 total.
Oldest change with at least one pending file transfer: 1234.
```

This can happen for a variety of reasons, most commonly:

- Non-existent (purged) files (where filetype includes +Sn - where n is number of revisions to keep contents for)
- Non-existent (shelved) files
- Non-existent files with verify problem on master server
- Temporary file transfer problems which exceeded thresholds for auto-retry

E.3.1. Resolutions

1. Retry pull errors

```
p4 pull -R

<wait a short time>

p4 pull -ls
```

2. If the above doesn't fix things then we can check for errors:

```
p4 pull -l | grep -c failed
```

3. If the above is > 0 then we need to investigate in more detail.

E.3.1.1. Remove and re-queue

Save the list of files with errors to a file - like this to allow for spaces in filenames:

```
p4 -F "%rev% %file%" pull -l > pull.errs
cat pull.errs | while read -e r f; do p4 pull -d -r $r -f "$f"; done
```

Finally we can “re-queue” any for re-transfer (note this can take a while for files with many revs):

```
cut -d' ' -f 2,999 pull.errs | sort | uniq | while read -e f; do echo "$f" && p4
verify -qt --only MISSING "$f"; done
```

the `--only MISSING` option requires `p4d` version `>= 2021.1` and is much faster - just remove that option with older versions of `p4d`

Then have another look:

```
p4 pull -l
```

E.3.1.2. Check for verify errors on the parent server

On the parent server, check the most recent `p4verify.log` file (typically runs Saturday morning via crontab).

Cross-check any entries in `pull.errs` above - if they are also verify errors on the parent server then you need to resolve that. Consider contacting helix-core-support@perforce.com if you need help. Resolutions may include obliterating lost revisions, or attempting to restore from backup.

E.4. Can't login to edge server

This can happen if the edge server replication has stalled as above.

E.4.1. Resolution

- Try the resolution steps for [Section E.2, “Replication appears to be stalled”](#)
- Restart edge server
- Monitor replication and check for any errors

E.5. Updating `offline_db` for an edge server

If your `daily_checkpoint.sh` jobs on the edge server are failing due to a problem with the `offline_db` or missing edge journals, AND the edge server is otherwise running fine, then consider this option.

Checkpointing the edge will take some time during which the edge will be locked! Schedule this for a convenient time!

E.5.1. Resolution

Assuming instance 1:

- ON EDGE SERVER:

```
source /p4/common/bin/p4_vars 1
p4 admin checkpoint -Z
```

- ON COMMIT SERVER (and at a convenient time to lock edge):

```
source /p4/common/bin/p4_vars 1
p4 admin journal
```

- Monitor edge server checkpoint being created (on EDGE SERVER):

```
p4 configure show journalPrefix
```

Using the output shown by the above command:

```
ls -lhr /p4/1/checkpoints.<suffix>/*.ckp.*
```

Also you can check for edge being locked (the following may hang):

```
p4 monitor show -al
```

- Then replay the journal on the edge server to the `offline_db`:

```
cd /p4/1/offline_db
mv db.* save/
nohup /p4/1/bin/p4d_1 -r . -jr /p4/1/checkpoints.<suffix>/p4_1.ckp.NNNN.gz >
rec.out &
```

When the above has completed, mark as usable by creating semaphore file:

```
touch /p4/1/offline_db/offline_db_usable.txt
```

E.6. Journal out of sequence in checkpoint.log file

This error is encountered when the offline and live databases are no longer in sync, and will cause the offline checkpoint process to fail. Because the scripts will replay all outstanding journals, this error is much less likely to occur. This error can be fixed by:

- recreating the `offline_db`: [Section 9.4.11, “recreate_offline_db.sh”](#)
- alternatively if that doesn’t work - run the [Section 9.4.6, “live_checkpoint.sh”](#) script (note the warnings about locking live database)

E.7. Unexpected end of file in replica daily sync

Check the start time and duration of the [Section 9.4.4, “daily_checkpoint.sh”](#) cron job on the master. If this overlaps with the start time of the [Section 9.6.33, “sync_replica.sh”](#) cron job on a replica, a truncated checkpoint may be rsync'd to the replica and replaying this will result in an error.

Adjust the replica's cronjob to start later to resolve this.

Default cron job times, as installed by the SDP are initial estimates, and should be adjusted to suit your production environment.

Appendix F: Starting and Stopping Services

There are a variety of *init mechanisms* on various Linux flavors. The following describes how to start and stop services using different init mechanisms.

F.1. SDP Service Management with the systemd init mechanism

On modern OS's, like RHEL7 & 8, Rocky Linux 8, and Ubuntu >=18.04, and SuSE >=12, the **systemd** init mechanism is used. The underlying SDP init scripts are used, but they are wrapped with "unit" files in `/etc/systemd/system` directory, and called using the **systemctl** interface as **root** (typically using **sudo** while running as the **perforce** user).

On systems where systemd is used, **the service can only be started using the `sudo systemctl` command**, as in this example:

```
sudo systemctl status p4d_N
sudo systemctl start p4d_N
sudo systemctl status p4d_N
```

Note that there is no immediate indication from running the start command that it was actually successful, hence the status command is run after. For best results, wait a few seconds after running the start command before running the status command. (If the start was unsuccessful, a good start to diagnostics would include running `tail /p4/N/logs/log` and `cat /p4/N/logs/p4d_init.log`).

The service should also be stopped in the same manner:

```
sudo systemctl stop p4d_N
```

Checking for status can be done using both the **systemctl** command, or calling the underlying SDP init script directly. However, there are cases where the status indication may be different. Calling the underlying SDP init script for status will always report status accurately, as in this example:

```
/p4/N/bin/p4d_N_init status
```

That works reliably even if the service was started with `systemctl start p4d_N`.

Checking status using the systemctl mechanism is done like so:

```
sudo systemctl start p4d_N
```

If this reports that the service is **active (running)**, such indication is reliable. However, the status indication may falsely indicate that the service is down when it is actually running. This could

occur with older init scripts if the underlying init script was used to start the server rather than using `sudo systemctl start p4d_N` as prescribed. The status indication would only indicate that the service is running if it was started using the systemctl mechanism. As of SDP 2020.1, a safety feature now assures that system is always used if configured.

F.1.1. Brokers and Proxies

In the above examples for starting, stopping, and status-checking of services using either the SysV or `systemd` init mechanisms, `p4d` is the sample service managed. This can be replaced with `p4p` or `p4broker` to manage proxy and broker services, respectively. For example, on a `systemd` system, the broker service, if configured, can be started like so:

```
sudo systemctl status p4broker_1
sudo systemctl start p4broker_1
sudo systemctl status p4broker_1
```

F.1.2. Root or sudo required with systemd

For SysV, having `sudo` is optional, as the underlying SDP init scripts can be called safely as `root` or `perforce`; the service runs as `perforce`.

If `systemd` is used, by default `root` access (often granted via `sudo`) is needed to start and stop the `p4d` service, effectively making `sudo` access required for the `perforce` user. The `systemd` "unit" files provided with the SDP handle making sure the underlying SDP init scripts start running under the correct operating system account user (typically `perforce`).

F.2. SDP Service Management with SysV init mechanism

On older OS's, like RHEL/CentOS 6, the SysV init mechanism is used. For those, you can the following example commands, replacing `N` with the actual SDP instance name

```
sudo service p4d_N_init status
```

The service can be checked for status, started and stopped by calling the underlying SDP init scripts as either `root` or `perforce` directly:

```
/p4/N/bin/p4d_N_init status
```

Replace `status` with `start` or `stop` as needed. It is common to do a `status` check immediately before and after a `start` or `stop`.

During installation, a symlink is setup such that `/etc/init.d/p4d_N_init` is a symlink to `/p4/N/bin/p4_N_init`, and the proper `chkconfig` commands are run to register the application as a service that will be started on boot and gracefully shutdown on reboot.

On systems using SysV, calling the underlying SDP init scripts is safe and completely interchangeable with using the `service` command being run as `root`. That is, you can start a service with the underlying SDP init script, and the SysV init mechanism will still safely detect whether the service is running during a system shutdown, and thus will perform a graceful stop if `p4d` is up and running when you go to reboot. The status indication of the underlying SDP init script is absolutely 100% reliable, regardless of how the service was started (i.e. calling the init script directly as `root` or `perforce`, or using the `service` call as `root`).

Appendix G: Brokers in Stack Topology

A preferred methodology is to deploy p4broker processes to control access to p4d servers. In a typical configuration, 100% of user activity gets to p4d thru a p4broker deployed in "stack topology", i.e. a p4broker exists on every machine where p4d is, and access to p4d on any given machine is only via the broker, with a typical setup using firewalls to enforce that concept. There are typically only 3 exceptions:

1. p4d-to-p4d communication (p4 pull, p4 journalcopy) bypasses the broker
2. Triggers called from p4d run 'p4' commands against the p4d port directly.
3. Admins running 'p4' commands while on the server machine can bypass the broker if they want.

Everything else (to include Proxies, Swarm, Jenkins, any systems integrations, etc.) must go thru the broker.

Using brokers like this makes it straightforward to implement the "Down for Maintenance" concept across an entire global topology. For example, when upgrade p4d services in a global topology, doing the outer-to-inner upgrade procedure, it is best to prevent users from loading the system during the upgrade process.

Using brokers in "stack topology" avoids the significant performance impact of brokers deployed on a different machine than the targeted p4d. While running on the same host, the impact of brokers is relatively small.

Brokers are preferred over p4d command triggers for certain use cases. They're independent of p4d and can keep p4d safe from rogue usage patterns.

Appendix H: SDP Health Checks

If you need to contact Perforce Support to analyze an issue with the SDP on UNIX/Linux, you can use the `/p4/common/bin/sdp_health_check.sh` script. This script is included with the SDP (starting with SDP 2023.1 Patch 3). If your installation does not have this script, it can be downloaded separately. Every version of the `sdp_health_check.sh` script can be used any and all versions of the UNIX/Linux SDP dating back to 2007, so you don't need to be concerned with version compatibility.

If your Perforce Helix server machine has outbound internet access, execute the following while logged in as the operating system user that owns the `/p4/common/bin` directory (typically `perforce` or `p4admin`):

```
cd /p4/common/bin
```

```
[[ -e sdp_health_check.sh ]] && mv -f sdp_health_check.sh  
sdp_health_check.sh.moved.$(date +%Y-%m-%d-%H%M%S')
```

```
curl -L -s -O https://swarm.workshop.perforce.com/projects/perforce-software-  
sdp/download/tools/sdp_health_check.sh  
chmod +x sdp_health_check.sh
```

```
./sdp_health_check.sh
```

If your Perforce Helix server machine does not have have outbound internet access, acquire the `sdp_health_check.sh` file from a machine that does have outbound internet access, and then somehow get that file to your Perforce Helix server machine.

If you have multiple server machines with SDP, possibly including machines running P4D replicas or edge servers, P4Proxy or P4Broker servers, run the health on al machines of interest.

The `sdp_health_check.sh` script will produce a log file that can be provided to Perforce Support to help diagnose configuration issues and other problems. The script has these characteristics:

- It is always safe to run. It does only analysis and reporting.
- It does only fast checks, and has no interactive prompts. Some log files are captured such as `checkpoint.log`, but not potentially large ones such as the `p4d` server log.
- It requires no command line arguments.
- It does not transfer sensitive information.
- It works for any and all UNIX/Linux SDP version since 2007.
